CUCM
Installation and Programming Manual

This Manual describes the CUCM Universal Communication Module, its uses and set up. It also describes the use of the programming software and compiler.

Effective: 13 May, 2004

Introduction

The Niobrara CUCM is a user programmable communication module for a Modicon TSX Compact Automation Series PLC. The user may write Applications to be loaded into the CUCM to communicate with serial and/or Ethernet devices. Applications are written as a text file in a "BASIC" like language developed specifically for writing serial protocols. The Applications are compiled and downloaded into FLASH memory in the CUCM. Up to two Applications may be loaded in the CUCM and run at the same time. Each Application has access to both serial ports, the Ethernet port (optional), and the Compact Backplane registers. Each Application may have up to 8 parallel tasking threads. Pre-written applications are also offered to cover some of the more common protocols including Modbus RTU and ASCII, SY/MAX, SY/MAX Net-to-Net, POWERLOGIC PNIM, RNIM Master and Slave, and IDEC. The CUCM interfaces to the Compact PLC as an I/O module and is thus permitted to be used in the Local (CPU rack), Remote (RIO), or Distributed (DIO) I/O racks. The CUCM is Traffic Copped as an analog module with up to 32 Input (3xxxxx) registers and 32 Output (4xxxxx) registers, or as a discrete module with up to 512 input bits (1xxxxx) and 512 coils (0xxxxx).

The CUCM is available in two models, the CUCM-O with two switch selectable RS-232/RS-485 serial ports and the CUCM-OE with two switch selectable RS-232/RS-485 ports and a 10BaseT Ethernet port.

Specifications

**Mounting Requirements**
One slot of Compact backplane.

**Maximum Backplane Addressing**
32 Words In
32 words Out

**Current Draw on Compact Rack power supply**
550 mA max. (350mA typical)

**Operating Temperature**
0 to 60 degrees C operating. -40 to 80 degrees C storage.

**Humidity Rating**
up to 90% noncondensing
Pressure Altitude
-200 to +10,000 feet MSL

Serial Communication Ports
Two 8-pin RJ45 connectors. User selectable baud rates up to 19.2Kbaud.
Front-panel switch selectable RS-232/RS-485 driver mode (Ports are independently selectable).

Ethernet Communication Port
10BaseT 8-pin RJ45 connector. Modbus/TCP (TCP/IP), SY/MAX 802.3 and other user configured protocols.

Memory
2 Application FLASH Areas with 128K bytes of Program size each with application 2 having a possible 256K bytes
32K bytes for Non-volatile Variable RAM memory
8K bytes of Application accessible FLASH
Two 128K bytes of Non-Volatile RAM memory as files.

Indicator lights
24 LEDs:
- Green Active, Ready, and Run
- Green E-net Collision, E-net Link, E-net Transmit, and E-net Receive
- Red Fault
- Green CF Active
- Green User lights 1 through 6
- Red User lights 7 and 8
- Green Application 1 RUN, and Application 2 RUN
- Green Port 1 Transmit and Receive
- Green Port 2 Transmit and Receive

Physical Dimensions
Wt.:2 lb. max
W: 1.5 in.
H: 5.4 in.
D: 4.3 in.

Real-Time Clock (RTC)
All CUCM’s have onboard a real-time clock, or RTC. The RTC’s data is displayed in Output registers 70 through 77. All values in registers 71 through 77 should be read as a decimal value. Register 71 displays the seconds, 72 displays the minutes, 73 displays the hours in a 24-hour format, 74 displays day of the month, 75 displays the month of the year, 76 displays the year, and 77 displays the day of the week. The day of the week is displayed as a number from 0 to 6, 0 being Sunday.

Register 70 displays the status of the data contained in these registers. A hex value of E000 indicates unreliable data. A value of C000 indicates reliable data. The data will be unreliable the first time the module is powered up, and each time the voltage supplied to the RTC drops below an acceptable level. The values in registers must then be set to the desired values, and a hex value of C5C5 should be written to register 70. This tells the RTC that the data has been set, and can now be treated as reliable.
LED Indicators and Descriptions

Figure 1-1 CUCM-OE Front Panel
Module Installation

1. Mount the CUCM at an angle onto the hook near the top of the backplane slot. Rotate the module down to make electrical contact to the backplane. Secure the screw at the bottom of the module. The maximum tightening torque for this screw is 2-4 in-lbs.

2. With power applied to the rack, all LEDs should strobe and when finished, the green Ready LED should illuminate and remain lit. This indicates that the CUCM has passed its internal self checks and is ready.

3. If the CUCM’s slot is properly rack addressed by the Compact, then the green Active LED should illuminate.

4. The green RUN LED will light if the slot is rack addressed and the Compact CPU is in RUN.

![Diagram of Module Installation](image)

**Figure 1-2 Mounting the CUCM on the Backplane**

Serial Installation

The CUCM connects to external RS-232 or RS-485 devices through its Port 1 or Port 2 RJ45 connectors.

Ethernet Installation

CUCM-OE units come with a 10BaseT Ethernet port. This port is to be connected to an Ethernet HUB using a standard CAT-5 twisted pair cable.

PLC Configuration

The number of addressed backplane registers needed by the CUCM completely depends upon the user applications. A maximum of 32 words of Input and 32 words of Output may be assigned to it by the Compact CPU. This assignment is accessed like other I/O modules through the Configure, Compact I/O screen in Modsoft, Concept, or other programming software. These registers are solely configured by the user’s applications and have no set meanings.

Software Installation

All files required to program and load the CUCM are located within the CUCM_SETUP.EXE file. This file is located on the CD provided with the CUCM, or at www.niobrara.com/html/httpfiles.html. From either of these locations, locate the Install Software pulldown menu, and select the CUCM from the list. When the setup program starts, the following screen will be displayed:
Contact information for Niobrara will be displayed, along with the option to continue or close. Click the Install button. The following screen will appear:

---

**Figure 1-3 CUCM Setup Opening Window**

This is the license agreement for use of Niobrara software. Click I Agree to continue. The following screen appears:

---

**Figure 1-4 CUCM Setup License Agreement**

To continue with this installation, you must agree to all terms of this license agreement.

---

**Figure 1-5 CUCM Setup Folder Selection**

This is the license agreement for use of Niobrara software. Click I Agree to continue. The following screen appears:
This is the point at which the user selects the folder into which all Niobrara files will be placed. Choose an appropriate location, or just select the default location, then click OK. The setup program will then extract all of the CUCM files, and place them in the selected folder. The following screen will then appear:

![Figure 1-6 CUCM Setup Finish Screen](image)

Click Ok to exit the setup software.
The user programs that run in the CUCM are known as Applications. Applications are written in the CUCM language with a text editor, compiled with the QCOMPILE program, and downloaded into the CUCM to run. The CUCM allows up to two Applications to run at the same time. Each Application has its own separate memory for variables as well as shared access to the PLC Rack I/O interface via the INPUT[x] registers and the OUTPUT[x] registers. These I/O words are the only directly common memory connection between the two Applications although Applications may share data through RAM files that are accessible using the READ FILE and WRITE FILE structures. Applications may be divided into multiple THREADs which multi-task within the Application. Up to eight THREADs may be written into an Application.

Each Application has full access to both serial ports, the optional Ethernet port, and as mentioned above the PLC I/O registers. Communication messages are sent from an Application using the TRANSMIT statement and are received with the ON RECEIVE statement. Built-in functions for calculating checksums are provided.

The general outline for a CUCM application is shown below:

```c
{Comments}
DECLARE global_variables
FUNCTIONS
{general startup configuration code}
THREAD 1
    DECLARE local_variables
    {thread 1 application code as an endless loop}
THREAD 2
    DECLARE local_variables
    {thread 2 application code as an endless loop}
```
Application code located before thread 1 is processed first as the application starts and then all threads start at the same time. Declares located before thread 1 are global and accessible in any of the threads. Declares within a thread are local only to that thread.

**Warning:** Applications that serve up web pages from the Compact backplane may be in violation of the following patents:

1. Patent no. 5,805,442
2. Patent no. 5,975,737
3. Patent no. 5,982,362
4. Patent no. 6,061,603
5. Patent no. 6,282,454

If you are writing an application that serves up web pages, you should contact Schneider Automation before proceeding.
The CUCM language is its own unique structured language, although the user will probably notice similarities with BASIC, PASCAL, and C. Labels are used to control program flow. Line numbers are not required. The following definitions apply through this manual:

**Constant Data Representation - <const>**

If numeric data is to remain the same during the entire operation of the CUCM program then they should be treated as constants. The CUCM supports unsigned decimal integers (16 bits), signed decimal integers, hexadecimal integers, long integers (32 bit), floating point numbers (32 bit), boolean constants, and a few reserved constants. The use of a constant is referred to as <const> in this manual.

**Table 3-1 Constant Data Types**

<table>
<thead>
<tr>
<th>Constant Data Type</th>
<th>Range</th>
<th>Prefix Symbol</th>
</tr>
</thead>
<tbody>
<tr>
<td>Decimal</td>
<td>0...65,535</td>
<td>NA</td>
</tr>
<tr>
<td>Signed Integer</td>
<td>-32768...32767</td>
<td>NA</td>
</tr>
<tr>
<td>Hexadecimal Integer</td>
<td>0...FFFF</td>
<td>x</td>
</tr>
<tr>
<td>Long Integers</td>
<td>0...4294967295</td>
<td>NA</td>
</tr>
<tr>
<td>Floating Point</td>
<td>8.43 x 10E-37... 3.402 x 10E38</td>
<td></td>
</tr>
<tr>
<td>Boolean Constants</td>
<td>TRUE, FALSE</td>
<td>NA</td>
</tr>
<tr>
<td>Reserved Constants</td>
<td>EVEN, ODD, NONE</td>
<td>NA</td>
</tr>
</tbody>
</table>

**Decimal Integers**

Decimal integers are defined as the unsigned whole numbers within the range from 0 through 65,535. The following are examples of decimal integers:

0
32114
59
65311
**Signed Integers**

Signed integers are defined as the whole numbers within the range from -32768 through 32767. The following are examples of signed integers:

-514  
0  
31  
-1

**Hexadecimal Integers**

Hexadecimal integers are defined as the hexadecimal representation of the whole numbers within the range from 0 through FFFF. Hexadecimal numbers are defined by the prefix x. The following are examples of hexadecimal constants:

x12AB  
xf34c  
x15

**Boolean Constants**

There are two predefined boolean constants: TRUE and FALSE. The following are valid uses of the boolean constants:

SET CAPITALIZE FALSE  
SET DEBUG TRUE

**Floating Point Numbers**

Floating point constants must end with a decimal point and at least one decimal place. The following are valid floating point examples:

-1.0  
3.14159  
2.5E-11

**Reserved Constants**

The following constants are reserved for the use in the SET PARITY statement: EVEN, ODD, and NONE. The following are valid uses of the reserved constants:

SET PARITY EVEN  
SET PARITY ODD  
SET PARITY NONE

**Variable Data Representation**

The CUCM uses alpha-numeric names for variables and each variable must be explicitly declared using the DECLARE statement. The possible variable types supported by the CUCM are listed below:

- BYTE (8 bits signed)  
- UNSIGNED BYTE (8 bits unsigned)  
- WORD (16 bits signed)  
- UNSIGNED WORD (16 bits unsigned)  
- LONG (32 bits signed)  
- TIMER (32 bits signed)  
- FLOAT (32 bits signed)  
- STRING (an array of 8 bit bytes)
• SOCKET (Ethernet IP socket)

If a type is not included in the DECLARE then the type defaults to a SIGNED WORD.

It is also possible to define single dimensional arrays of variables using the form variable[size], and two-dimensional arrays using the form variable[Asize, Bsize]. Valid array indices for array[N] are 0..(N-1).

Multiple variables may be declared on a single statement with commas as separators. The following statements are valid DECLARE examples:

DECLARE BYTE apple
DECLARE WORD x, y, zebra
DECLARE WORD r[100], group[10]
DECLARE SOCKET s[8], mysock
DECLARE STRING in[25]
DECLARE WORD a, b, c FLOAT x, y, z {the , after the c is optional. a, b, and c are words and x, y, and z are floats.}

There are two predefined arrays of words that are fixed and reserved: INPUT[x] and OUTPUT[x]. The INPUT[x] array ranges from index 0 through 31 inclusive and refers to the 32 possible PLC input (3x) registers on the backplane. These words are PLC Read-Only and may be modified only by the CUCM applications. The OUTPUT[x] array ranges from index 0 through 2015. Index values 0 through 31 are reserved for the 32 possible PLC OUTPUTs (4x registers) and are Read-Only to the CUCM applications. OUTPUT[32] through OUTPUT[2015] are Read/Write by the CUCM Applications.

The OUTPUT and INPUT variables are global to both Applications and all Threads within the Applications. Variables declared before the first THREAD statement are global to a given Application. Variables declared within a THREAD are local to that Thread.

### Arithmetic Expressions - <expr>

Numeric expressions, referred as <expr> in this manual, involve the operation of variables and constants through a precedence of operators and functions.

#### Numeric Operators

<table>
<thead>
<tr>
<th>Numeric Operator</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>+</td>
<td>Addition</td>
<td>x + 5</td>
</tr>
<tr>
<td>*</td>
<td>Multiplication</td>
<td>apple * 5</td>
</tr>
<tr>
<td>/</td>
<td>Division</td>
<td>z / 5</td>
</tr>
<tr>
<td>%</td>
<td>Modulus</td>
<td>OUTPUT[25] % 5</td>
</tr>
<tr>
<td>&amp;</td>
<td>Bitwise AND</td>
<td>OUTPUT[25] &amp; x100</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bitwise OR</td>
</tr>
<tr>
<td>^</td>
<td>Bitwise Exclusive OR</td>
<td>INPUT[25] ^ x100</td>
</tr>
<tr>
<td>&gt;&gt;</td>
<td>Bitwise Shift Right</td>
<td>BYTE &gt;&gt; 4</td>
</tr>
<tr>
<td>&lt;&lt;</td>
<td>Bitwise Shift Left</td>
<td>1 &lt;&lt; 2</td>
</tr>
<tr>
<td>-</td>
<td>Unary Negation</td>
<td>-OUTPUT[25]</td>
</tr>
<tr>
<td>~</td>
<td>Unary Bitwise Complement</td>
<td>-OUTPUT[25]</td>
</tr>
<tr>
<td>(</td>
<td>Parentheses</td>
<td>(OUTPUT[25] + 5) * 3</td>
</tr>
</tbody>
</table>

#### Precedence of Operators

The order of precedence of supported numeric operators are as follows:
Sub expressions enclosed in parentheses

Unary Negation or Unary Complement

* / % From left to right within the expression.

+ - From left to right within the expression.

<< >> From left to right within the expression.

& | From left to right within the expression.

**Numeric Functions**

The CUCM supports a group of seven checksum calculating functions to be used only within message descriptions:

**Table 3-3 Checksum Functions**

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CRC(&lt;expr&gt;,&lt;expr&gt;,&lt;expr&gt;)</td>
<td>Cyclical Redundancy Check (CCITT Standard)</td>
</tr>
<tr>
<td>CRC16(&lt;expr&gt;,&lt;expr&gt;,&lt;expr&gt;)</td>
<td>Cyclical Redundancy Check</td>
</tr>
<tr>
<td>CRCAB(&lt;expr&gt;,&lt;expr&gt;,&lt;expr&gt;)</td>
<td>Special CRC16 for A-B applications</td>
</tr>
<tr>
<td>CRCBOB(&lt;expr&gt;,&lt;expr&gt;,&lt;expr&gt;)</td>
<td>Special CRC16 for BinMaster SmartBob applications</td>
</tr>
<tr>
<td>CRCDNP(&lt;expr&gt;,&lt;expr&gt;,&lt;expr&gt;)</td>
<td>Special CRC16 for DNP 3.00 applications</td>
</tr>
<tr>
<td>LRC(&lt;expr&gt;,&lt;expr&gt;,&lt;expr&gt;)</td>
<td>Longitudinal Redundancy Check by byte</td>
</tr>
<tr>
<td>LRCW(&lt;expr&gt;,&lt;expr&gt;,&lt;expr&gt;)</td>
<td>Longitudinal Redundancy Check by word</td>
</tr>
<tr>
<td>SUM(&lt;expr&gt;,&lt;expr&gt;,&lt;expr&gt;)</td>
<td>Straight Sum by byte</td>
</tr>
<tr>
<td>SUMW(&lt;expr&gt;,&lt;expr&gt;,&lt;expr&gt;)</td>
<td>Straight Sum by word</td>
</tr>
</tbody>
</table>

The first <expr> is the starting index. The next <expr> is the ending index. The last <expr> is the initial value usually 0 or -1.

These additional functions are also provided:

**Table 3-4 Additional Functions**

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>Example OUTPUT[45]=x1234, OUTPUT[46]=xABCD</th>
</tr>
</thead>
<tbody>
<tr>
<td>MIN(&lt;expr&gt;,&lt;expr&gt;)</td>
<td>Provides a result of the &lt;expr&gt; which evaluates to the smaller of the two expressions.</td>
<td>OUTPUT[100] = MIN(OUTPUT[45],OUTPUT[46]) results in OUTPUT[100] = x1234</td>
</tr>
<tr>
<td>MAX(&lt;expr&gt;,&lt;expr&gt;)</td>
<td>Provides a result of the &lt;expr&gt; which evaluates to the larger of the two expressions.</td>
<td>OUTPUT[100] = MAX(R[45]*x0A,OUTPUT[47]) results in OUTPUT[100] = x65E0</td>
</tr>
<tr>
<td>SWAP(&lt;expr&gt;)</td>
<td>Reversed the byte order of the register.</td>
<td>OUTPUT[100] = SWAP(OUTPUT[46]) results in OUTPUT[100] = xCDAB</td>
</tr>
</tbody>
</table>

**Labels - <label>**

The CUCM supports alphanumeric labels for targets of GOTO and GOSUB functions. The label consists of a series of characters ended with a colon. Labels must start with a alphabetic character, numbers are not allowed as the first character in a Label. Labels may not be the exact characters in a CUCM language reserved word. The label TIMEOUTLoop: is valid while TIMEOUT: is not valid.

**Logical Expressions - <logical>**

The CUCM supports the following logical operators and relational operators. These are referred to as <logical> elsewhere in this manual.
Logical Operators

Table 3-5 Logical Operators

<table>
<thead>
<tr>
<th>Logical Operator</th>
<th>Definition</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>AND</td>
<td>Result TRUE if both TRUE</td>
<td>IF &lt;expr&gt; AND &lt;expr&gt; THEN</td>
</tr>
<tr>
<td>OR</td>
<td>Result TRUE if one or both TRUE</td>
<td>IF &lt;expr&gt; OR &lt;expr&gt; THEN</td>
</tr>
<tr>
<td>NOT</td>
<td>Inverts the expression</td>
<td>IF NOT(&lt;expr&gt;) THEN</td>
</tr>
</tbody>
</table>

Relational Operators

Table 3-6 Relational Operators

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

Functions - <function>

Functions are general purpose sections of code that may be accessed from multiple threads and other functions in an application. Functions are similar to a subroutine where the parameters are passed to/from the function during the call.

Memory for variables declared within a function are allocated when the function is called, and the memory is freed when the function exits. Variable names within a function can have the same name as global or thread local variables. When a variable is referenced within a function, the compiler checks first for function local variables, then for thread local variables, then for global variables by that name.

NOTE: At the present time, only "word" variables may be passed as parameters to functions. If the function must process long, byte, string, float, or arrays then they must be declared as global.

FUNCTION <function name> <comma separated variable list>
  (function body)
ENDFUNC <returned variable list>

FUNCTION AVERAGE ( VALUE1, VALUE2 )
  DECLARE WORD RETURNVALUE
  RETURNVALUE = ( VALUE1 + VALUE2 ) / 2
ENDFUNC( RETURNVALUE )

--or--

FUNCTION SQUARE ( VALUE)
ENDFUNC ( VALUE * VALUE)
Message Descriptions - <message description>

The <message description> refers to the actual serial data that is transmitted from the CUCM port or expected data that is to be received by the port. The <message description> may include literal strings, results of various message functions and the concatenation of the above.

Literal String - <string>

A literal string is a string enclosed in quotes. "This is a literal string."

Literal strings may include hexadecimal characters by form \xx where xx is the two digit hex number of the character. This is useful for sending non-printable characters. "This is another literal string.\0D\0A" will print the message with a carriage return (0D) and a line feed (0A).

Embedded quotation marks may be included in literal strings by the insertion of \" in the location of the embedded quote. "This will print a \"quote\" here."

Embedded \ characters may similarly be inserted by using \\.

String Variables

String variables may be embedded directly into a message description:

DECLARE STRING ALPHA[20]
ALPHA = "ABC123"
TRANSMIT PORT 1 "=BEFORE=:ALPHA=:AFTER=

would send the string =BEFORE=ABC123=AFTER= out serial port 1. Similarly, string variables may be embedded directly into ON RECEIVE statements:

ON RECEIVE PORT 1 ALPHA:"\0D" GOTO NEXT

would place all characters received before the Carraige Return ( 0x0D ) into the string variable ALPHA. Care must be taken to ensure that the data read into the string is not longer than the string declaration. For instance, if the above ON RECEIVE were to attempt to put 21 characters into ALPHA, which was declared with a length of 20 bytes, the program would halt, with runtime stop code 7 (Value out of bounds).

Message Functions

The CUCM can perform a variety of functions on transmitted and received data. When the CUCM is using these functions for transmitting, register data and expressions are turned into strings according to the function’s rules. When the CUCM is using these functions for receiving, incoming strings are either matched to the strings that the CUCM expected to receive or they are translated into data and stored in registers.

The following is a list of message functions, each function is described in more detail on pages 42 through 44.
Table 3-7  Message Functions

<table>
<thead>
<tr>
<th>Functions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BCD(&lt;expr&gt;)</td>
<td>Binary Coded Decimal conversion</td>
</tr>
<tr>
<td>BYTE(&lt;expr&gt;)</td>
<td>Least Significant (low) byte conversion</td>
</tr>
<tr>
<td>DEC(&lt;expr&gt;,&lt;expr&gt;)</td>
<td>Decimal conversion (base 10) -32768 to 32767</td>
</tr>
<tr>
<td>HEX(&lt;expr&gt;,&lt;expr&gt;)</td>
<td>Hexadecimal conversion (base 16)</td>
</tr>
<tr>
<td>IDEC(&lt;expr&gt;,&lt;expr&gt;)</td>
<td>IDEC format hexadecimal conversion</td>
</tr>
<tr>
<td>OCT(&lt;expr&gt;,&lt;expr&gt;)</td>
<td>Octal conversion (base 8)</td>
</tr>
<tr>
<td>RAW(&lt;variable&gt;,&lt;expr&gt;)</td>
<td>Sends/Receives high byte then low byte of a register(s)</td>
</tr>
<tr>
<td>RWORD(&lt;expr&gt;)</td>
<td>Sends/Receives low byte of an expression</td>
</tr>
<tr>
<td>UNS(&lt;expr&gt;,&lt;expr&gt;)</td>
<td>Unsigned decimal conversion (base 10) 0 to 65,535</td>
</tr>
<tr>
<td>WORD(&lt;expr&gt;)</td>
<td>Sends/Receives high byte then low byte of an expression</td>
</tr>
</tbody>
</table>

The message functions that take the form \( FUNC(<expr>,<expr>) \) use the following rules: When using these functions with TRANSMIT, the first \(<expr>\) is the data to be translated and transmitted. When using these functions with ON RECEIVE, replace the first \(<expr>\) with \(<variable>\) to have the incoming string translated and placed into the register OUTPUT[] or use \(<expr>\) to have the expression evaluated and matched to the incoming string. The second \(<expr>\) in these functions is the number of characters either to transmit or to receive. An error will be generated at compile or run time if this expression evaluates to less than zero.

RAW takes the form \( RAW(<variable>,<expr>) \). In this case the first \(<expr>\) is the starting register number and the second \(<expr>\) is the number of characters. Always uses the high byte first and then the low byte.

The message functions that take the form \( FUNC(<expr>) \) have fixed character lengths. BYTE transmits one character, the least significant byte, while WORD and RWORD each transmit two characters. WORD transmits the most significant byte and then the least significant byte while RWORD reverses the order, least significant then most significant. As in the previous message functions, when transmitting use \(<expr>\) and when receiving either use \(<variable>\) to receive and place in a register or \(<expr>\) to evaluate and match. For examples of the message functions see Chapter 6 - Examples.

In all of the message functions, only characters from the valid character set for that command can be used.

Variable Fields

The width field of any transmit or receive element (that has a width) may be replaced with either of two constructions. (Transmit RAW is an exception as shown below.) The first is just the word VARIABLE, i.e. TRANSMIT DEC(OUTPUT[10],VARIABLE). The second is VARIABLE followed by a register reference, i.e. TRANSMIT HEX(OUTPUT[11],VARIABLE OUTPUT[10]) which will write the actual width to the specified register

Transmit usage of Variable length

A variable field in a TRANSMIT statement means one encoded with only the necessary number of digits (no leading zeros).

For example, if OUTPUT[11] = 1234 then

\[
\text{TRANSMIT PORT 1 "$":DEC(OUTPUT[11], variable OUTPUT[10]):"#"}
\]

would send out the string $1234# and OUTPUT[10] would have the value 4. If OUTPUT[11] = 89 then the string $89# would be transmitted and OUTPUT[10] would equal 2.

This type of transmit structure applies to the BCD, UNS, DEC, HEX, OCT, and IDEC formats. The TRANSMIT RAW variable structure requires a terminator byte of 00 hex at the end of the raw string.
The transmit raw variable sends up to but not including the null terminator. The optional count register does not include the terminator in the count.

TRANSMIT PORT 1 "$":RAW(OUTPUT[11], VARIABLE OUTPUT[10]):"#"

would send the string $Howdy# and OUTPUT[10] would equal 5. If OUTPUT[12]=x0000 then the string $Ho# would be transmitted and OUTPUT[10] would equal 2.

ON RECEIVE usage of Variable length
A variable field in an ON RECEIVE statement must be followed by a literal field such as "/0d". The first character of the literal field works as a terminator.

For example, A device sends a variable length number with a fixed number of decimal points such as $125.01 or $3.99; the decimal point may be used as a terminator and it could be handled as follows:

ON RECEIVE port 1 "$":dec(OUTPUT[100],variable):":":dec(OUTPUT[101],2)

The ON Receive raw variable writes an extra zero byte to the registers following the received data. In the case of an odd number of characters, the last register contains the final character in the MSB and a zero in the LSB. In the case of an even number of characters, all 16 bits of the register following the last two characters are set to zero. This null terminator is not included in the count optionally reported.

For example: A device transmits a variable length error message terminated with a carriage return and line feed.

ON RECEIVE port 1 RAW(OUTPUT[500], variable OUTPUT[200]):"/0d/0a"

will accept the message and place it in packed ASCII form starting at register 500. Register 200 would hold the number of characters (bytes) accepted in the string not including the carriage return or line feed.

Message Assignments
It is sometimes convenient to apply the message descriptions of a TRANSMIT message and store the message in a variable in the CUCM rather than transmit the string. This is possible by simply using the assignment character = to a string variable.

STRINGVARIABLE = <message>

The message will be placed in the string variable and the LENGTH of the string will be set to the number of character is <message>. Any valid transmit message may be stored in this manner.

For example:

STRINGVAR = "Hello!/0d/0a"

would result in the string STRINGVAR containing the string "Hello!/0d/0a" (where /0d and /0a are Carriage Return, and Line Feed, respectively).

Something more obviously useful might be:

STRINGVAR = byte( Device):"/03":word( Address):word( Count):rword(crc16(1,$-1,0))

which would place the reversed word of the checksum in register at the end of the string.
The CUCM language statements are described in this chapter. Statements control the operation of the CUCM by determining the flow of the program.

The format of these statements includes the definitions from Chapter 3 - CUCM Language Definitions. Whenever one of these definitions is referenced in a statement it is enclosed in brackets <>. For example, whenever a statement requires an expression it will appear as <expr>. The words statement and command are used interchangeably.

The word newline means a carriage return, line feed or both, whatever your text editor requires. Most commands do not require newlines but those that do use the word newline. Since most commands do not require newlines, multiple statements can be placed on a single line. A whole program could be written on a single line if no statements that require a newline are used. For readability, newlines between statements can be used without penalty.

Also note that, except in strings, capitalization in the CUCM program is ignored by the CUCM and its compiler. The label Tom: is the same as the label TOM:. In literal strings, which are enclosed in quotes "", the capitalization is maintained by the CUCM. The command SET CAPITALIZE can effect the way the CUCM handles ASCII characters on transmitting and receiving.

Program flow within a THREAD is sequential, from the first statement to the second statement to the third statement etcetera, unless a program flow control statement is reached. Program flow statements can be jumps (GOTO or GOSUB), loops or conditionals (IF...THEN...ELSE...ENDIF). After a jump, program flow is still sequential starting with the statement immediately after the label. Loops can be accomplished with FOR...NEXT, REPEAT...UNTIL, or WHILE...WEND.

### Assignments

The CUCM language allows for the assignment of values to variables and bits of variables. These assignments are similar to the BASIC LET statement.

**variable[expr]=expr**

This statement sets the variable specified by the first <expr> to the value obtained by the second <expr>. The valid range of variable numbers in the first <expr> is dependent upon the DECLARED range of the variable.

**variable[expr].[const]=logical**

This statement sets a single bit of a variable to be one (TRUE) or zero (FALSE). The <expr> can
have the values defined by the DECLARE of the variable. The valid values for <const> depend on
the type of <Expr> (see Table 5-1, below). <Logical> can have the values TRUE or FALSE.

### Table 4-1 Referencing Bits in Different Variable Types

<table>
<thead>
<tr>
<th>Variable Type</th>
<th>Range of Bits</th>
<th>Bit Significance</th>
</tr>
</thead>
</table>
| OUTPUT[N] and INPUT[N] | 1...16        | Modicon Bit Numbering: Most Significant Bit
|                     |               | (MSB) = Bit 1 ... LSB = Bit 16                        |
| BYTE                | 0...7         | IEC Compliant Bit numbering:
|                     |               | MSB = Bit 7 ... LSB = Bit 0                           |
| WORD                | 0...15        | IEC Compliant Bit numbering:
|                     |               | MSB = Bit 15 ... LSB = Bit 0                          |
| LONG, TIMER         | 0...31        | IEC Compliant Bit numbering:
|                     |               | MSB = Bit 31 ... LSB = Bit 0                          |

<variable>.(<expr>)=<logical>

This statement sets the bit of a register to be the evaluation of the <logical> segment.

<variable>.<variable>=<logical>

This statement sets the bit of a register to be the evaluation of the <logical> segment.

<variable>=<message description>

This statement sets the string variable specified by the <expr> to the ASCII values obtained by
evaluation of the <message description>. The <message description> may be any valid message
used in a TRANSMIT command.

### BAUD

See SET BAUD on page 32.

### CAPITALIZE

See SET CAPITALIZE on page 32.

### CLEAR

CLEAR variable[<expr>].<const> or CLEAR variable[<expr>].(<expr>)

The CLEAR statement sets a single bit of a variable to ZERO. The bit number <const> or <expr>
must evaluate within the range of 1-16 for OUTPUT registers, 0-7 for bytes, 0-15 for words, and
0-31 for long variables. To clear a single bit of a register to be set to one use the SET statement.

### CLOSE

CLOSE SOCKET <socket variable> [ TIMEOUT <expr>]

Closes the open IP connection associated with <socket variable>. The optional TIMEOUT specifies
how long the CUCM TCP/IP stack will wait for the other device to acknowledge the request to
close the connection before aborting (resetting) the connection. If no TIMEOUT is specified, the
CUCM will wait indefinitely for the other device to acknowledge the close request. A TIMEOUT
value of zero will cause the connection to be immediately closed, without the other devices’ ac-
knowledgement.

### CONNECT

CONNECT <protocol> SOCKET <socket variable> <IP Address> PORT <port number>

Connect opens an IP connection using the <protocol> to the remote <IP Address> on the <port...
number>.
NOTE: Only <protocol>= TCP is presently supported.
The <IP Address> must be a comma separated decimal notation:
DECLARE SOCKET S, BYTE HOST[4]
HOST = 206.223.51.161
CONNECT TCP SOCKET S HOST PORT 80
would establish a connection to port 80 of the device with IP address 206.223.51.161.

DATA
See SET DATA on page 33.

DEBUG
See SET DEBUG on page 33.

DECLARE

DECLARE [SIGNED|UNSIGNED] [<variable type>] <variable name>[<array size>]
The DECLARE statement is a compiler instruction which creates a variable named <variable name> of type <variable type>. Variables may be declared anywhere in the program, as long as they are declared before they are referenced. Variables declared before the first THREAD statement will be global in scope, thus will be accessible to all the threads. Variables declared after a THREAD statement will be accessible only within the thread in which it was declared. Variables declared within a FUNCTION will be accessible only within that function.
If the SIGNED/UNSIGNED specification is omitted, the variable created will be SIGNED. If the <variable type> is omitted, a WORD variable will be created. Thus the statement:
   DECLARE FOO
will create a variable named FOO, which is a signed word variable. Multiple variable types may be declared in one DECLARE statement:
   DECLARE BAR, STRING A[40], B[30], FLOAT X, Y[10]
would create five variables: BAR is a signed word, A is a string with maximum length of 40 bytes, B is a string with a maximum length of 30 bytes, X is a floating point variable, and Y is an array of ten floating point variables (Y[0] ... Y[9]).
When a variable is referenced (i.e. Y[0] = 0.0), the compiler first checks whether the variable is a function local variable (if the statement is inside a function), then checks whether the variable is a thread local variable (if the statement is multi-threaded, and the statement appears after a THREAD statement), then checks whether the variable was defined as a global variable. Thus, the same variable name may be used in different threads, and each thread will access a different variable.
The available <variable types> are:
Table 4-2  Declared Variable Types

<table>
<thead>
<tr>
<th>Variable Type</th>
<th>Description</th>
<th>Bytes Used</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>

<td>1538</td>
<td></td>
</tr>
</tbody>
</table>

DEFINE

DEFINE <macro>=<replacement string> newline

The DEFINE statement is a compiler instruction for a global find and replace. When the CUCM program is compiled the compiler finds every string <macro> and replaces it with the the string <replacement string>. Both <macro> and <replacement string> are type <string>. A newline is required to define the end of the replacement string. Use of this statement can help the readability of the user program and also make the program easier to write.

DELAY

DELAY <expr>

The DELAY statement forces the CUCM to pause in its execution of other instructions until a period of time equal to <expr> times 1mS has expired. Valid range is 0 to xFFFFFFFF.

DUPLEX

See SET DUPLEX on page 33.

ERASE

ERASE <variable>

The ERASE command initializes a variable or array to zero.
EXPIRED

ON EXPIRED(<variable>) GOTO <variable>

IF EXPIRED(<variable>) THEN <expression>

The EXPIRED command is used in conjunction with a declared timer to allow the user to perform other functions based on a timeout. A timer is declared, and a value in milliseconds is assigned in one or two commands. The user can then use the EXPIRED command to check if the timer has run out.

FOR...NEXT

The FOR ... NEXT statement provides the ability to execute a set of instructions a specific number of times. The variable <variable> is incremented from the value of the first <expr> to the value of the second <expr>. Once the variable is greater than the second <expr>, control passes to the next program statement following the NEXT. If the optional STEP expression is included, the variable <variable> is incremented by the value equal to the STEP <expr>. If the STEP <expr> is not present a step of 1 is assumed.

FOR <variable>=<expr> TO <expr>
one or more statements
NEXT

FOR <variable>=<expr> TO <expr> STEP <expr>
one or more statements
NEXT

FOR ... NEXT loops may be constructed to decrement from the first <expr> to the second <expr> using the DOWNTO function. The STEP <expr> must be a negative number. If STEP <expr> is not present a step of -1 is assumed.

FOR <variable>=<expr> DOWNTO <expr>
one or more statements
NEXT

FOR <variable>=<expr> DOWNTO <expr> STEP <expr>
one or more statements
NEXT

FOR...NEXT loops may be nested any number of levels.

FLUSH

FLUSH PORT x

The FLUSH statement empties the receive buffer for the specified port.

GOSUB...RETURN

GOSUB <label>

The GOSUB statement turns control of a program to another area of code while expecting to get control back from a RETURN statement. It is useful for program flow control where one section of code may be used several times. Somewhere in the program flow following <label> needs to be a RETURN statement. The RETURN statement returns program control back to the GOSUB statement that caused the jump. After a RETURN the CUCM will continue running using the statement immediately following the GOSUB.

GOTO

GOTO <label>

The GOTO statement turns program control over to another area of code.
The IF ... THEN statement is used to control the program flow based upon the logical evaluation of the expression in `<logical>`. When `<logical>` is true, the statements following the THEN are executed. If `<logical>` is false the statements following the ELSE are executed.

```
IF <logical> THEN one or more statements followed by newline
IF <logical> THEN one or more statements ELSE one or more statements followed by a newline
```

When more statements are required for an IF ... THEN, the statements may be placed on additional lines below the IF ... THEN. The ENDIF statement indicates the termination of the IF statement.

```
IF <logical> THEN newline
one or more statements
ENDIF
IF <logical> THEN newline
one or more statements
ELSE
one or more statements
ENDIF
```

**LIGHT**

See SET LIGHT on page 33.

**LISTEN**

```
LISTEN <protocol> SOCKET <socket number> PORT <protocol port number>
```

The listen command instructs the Ethernet port to use a socket to listen for a particular protocol on a given port number. Presently only the TCP protocol is supported.

Example: LISTEN TCP SOCKET mysock PORT 502

Common TCP port numbers are shown in Table 4-3.

**Table 4-3 Well Known TCP Port Numbers**

</tbody>
</table>

1 Internet Protocols are available as Requests For Comment (RFCs). They are available on the Internet via HTTP: http://www.rfc-editor.org
2 The Modbus/TCP specification is available http://www.modicon.com/openmbus/

**MOVE**

Reserved instruction for a special NR&D motion control application. Must not be used in user application.

**MULTIDROP**

See SET MULTIDROP on page 34.
ON CHANGE

ON CHANGE <variable> GOTO <label>
ON CHANGE <variable> RETURN
ON CHANGE <variable> & <expr> GOTO <label>
ON CHANGE <variable> & <expr> RETURN

The ON CHANGE statement functions within a WAIT loop (like an ON RECEIVE or ON TIMEOUT), and performs the GOTO or RETURN depending upon the result of the value of <variable>. When the value in <variable> is modified by another source, the ON CHANGE statement is performed.

ON <expression>

ON <expression> GOTO
ON <expression> RETURN

When the expression evaluates TRUE the wait loop is exited and flow proceeds to the GOTO or RETURN.

ON RECEIVE PORT x

ON RECEIVE SOCKET x

ON RECEIVE port 1 <message description> GOTO <label>
ON RECEIVE socket <socket name> <message description> GOTO <label>
ON RECEIVE port 2 <message description> RETURN
ON RECEIVE SOCKET <socket name> <message description> RETURN

The ON RECEIVE statement functions within a WAIT loop and performs the GOTO or RETURN depending upon whether the incoming string exactly matches the <message description>.

ON TIMEOUT

ON TIMEOUT <expr> GOTO <label>
ON TIMEOUT <expr> RETURN

The ON TIMEOUT statement functions within a WAIT loop (like an ON RECEIVE or ON CHANGE), and performs the GOTO or RETURN depending upon the elapsed time between incoming characters on the port. The result of the <expr> must fall within the range 0 to FFFF hex. Like the DELAY function, the ON TIMEOUT <expr> waits for a period of time equal to <expr> times 1mS.

PARITY

See SET PARITY on page 34.

READ FILE

READ FILE <file number> OFFSET <offset value> <variable,variable,...>

The READ FILE statement allows a CUCM program to read memory from the 6x file areas of the CUCM to the user memory area.

The <file number> is an expression which evaluates a number in Table 4-4.
The <offset> is an expression which evaluates to the byte location for the start of the read.

*NOTE: CUCM-SE RAM block 1 at file 768 is only 16K bytes and block 2 does not exist. Attempting to access these RAM areas will result in a runtime error.

**REPEAT**...**UNTIL**

REPEAT

program statements

UNTIL <logical>

The REPEAT statement starts a loop based upon the evaluation of the <logical> condition located in the UNTIL statement. The loop will only be performed as long as the <logical> is FALSE. When the <logical> is TRUE, program execution jumps to the statement following the UNTIL.

Note: The program statements will execute at least once regardless of the condition of <logical>. This is different than the WHILE...WEND or FOR...NEXT loops which only execute while the <logical> is TRUE, and will not execute the program statements within their boundaries if the <logical> is FALSE.

**RETURN**

See **GOSUB**...**RETURN** on page 29.

**SET**

The SET statement allows the initialization of the CUCM for the following parameters: Baud rate, Capitalization of incoming characters, Data bits, Parity, Stop bits, and Debug mode. SET must be followed by the serial port number for the action to take place.

**SET PORT x BAUD <const>**

The SET BAUD statement sets the baud rate of the port for the value. Any decimal value may be chosen for the baud rate. Example: SET PORT 1 BAUD 9600

**SET PORT x CAPITALIZE <const>**

**SET SOCKET x CAPITALIZE <const>**

The SET CAPITALIZE statement performs a translation on incoming ASCII alphabet characters from the lower case to the upper case. Example: SET PORT 2 CAPITALIZE TRUE or SET PORT 1 CAPITALIZE FALSE.
**SET PORT x CTS <const>**

The SET CTS statement sets the operation of the CTS pin on the RS-232 port. Possible values are:

- **CTS ON** - This is the normal mode of CTS where CTS must be asserted to allow the serial port to transmit.
- **CTS OFF** - Allows the use of the CTS pin to be independently monitored for its state while the serial port is allowed to transmit regardless of the state of CTS. This operation is very useful in modem applications where CTS is wired to DCD on the modem so the CUCM can tell if the modem has carrier.

**SET PORT x DATA <const>**

The SET DATA statement sets the number of data bits for the operation of the port. Valid range is 5, 6, 7, or 8 bits. Example: SET PORT 1 DATA 8

**SET DEBUG <const>**

The SET DEBUG statement determines the operation of the CUCM port in the event of a run time error. If SET DEBUG TRUE is used, the CUCM program will halt upon a run time error and display the error number and line number in the appropriate registers. If SET DEBUG FALSE is used, the CUCM program will halt upon a run time error and immediately restart the program from the beginning.

**SET PORT x DUPLEX <const>**

The SET DUPLEX statement determines the operation of the port’s receiver. With DUPLEX HALF, the receiver is only turned on when the port is not transmitting. With DUPLEX FULL, the receiver is always on. DUPLEX HALF should be used in 2-wire applications.

**SET LIGHT <exp> <const>**

The SET LIGHT statement is used to determine the state of the 10 indicator lights for the CUCM. SET LIGHT 1 ON turns on the light while SET LIGHT 1 OFF turns off the light. See also TOGGLE LIGHT on page 36.

**SET MODE <const>**

The SET MODE statement determines the operating mode of the port. Valid entries are UCM, RTU, SYMAX, RNIM, and PPP.

UCM mode allows the use of raw TRANSMIT and RECEIVE statements to communicate with the external device. Example: TRANSMIT PORT 1 "Example string"

RTU mode gives the CUCM more automatic control of the TRANSMIT and RECEIVE statements. This mode lets the CUCM assume that the communication will be Modbus RTU. The programmer will create a Modbus packet in a byte array, then hand the CUCM a length and the name of the array. During TRANSMIT, the CUCM will calculate and append the checksum to the end of the packet. During RECEIVE, the CUCM will watch for the 3.5 character timeout, then verify the checksum. The CUCM will then replace the data in the array with the new data from the reply.

```
DECLARE UNSIGNED BYTE CMD[100]
DECLARE WORD CMDLEN
...
TRANSMIT PORT 1 WORD(CMDLEN):RAW(CMD, CMDLEN)
ON RECEIVE PORT 1 WORD(CMDLEN):RAW(CMD, CMDLEN) GOTO <variable>
```

SYMAX mode works on the same principle as RTU mode. The CUCM will assume that the following communication is SY/MAX, and will handle checksums, ACK’s, DLE escapes, etc., involved in SY/MAX communications. During TRANSMIT, the programmer will hand the CUCM the length of the SY/MAX packet data, the SY/MAX route escaped by xFF, and the SY/MAX packet data. During RECEIVE, the CUCM will hand the programmer, the length of the reply, the route escaped by xFF, and the SY/MAX reply data.
DECLARE STRING ROUTE[16], REPLYDATA[200]
DECLARE WORD REMOTE, COUNT, REPLYLEN
...
TRANSMIT PORT 1 WORD(6):RAW(ROUTE,LENGTH(ROUTE))::FF::"0003":
WORD(REMOTE):WORD(COUNT)
ON RECEIVE PORT 1  WORD(REPLYLEN)::11::RAW(ROUTE,4)::FF::"8603":
WORD((REMOTE)):RAW(REPLYDATA,REPLYLEN-4) GOTO <variable>

RNIM mode is nearly identical to SYMAX mode. The only differences are the addition of a Network ID, transaction number, and a drop before the route.

DECLARE STRING ROUTE[16], REPLYDATA[200]
DECLARE WORD DROP, TRANSNUM, REMOTE, COUNT, REPLYLEN
...
TRANSMIT PORT 1 WORD(6):BYTE(DROP):BYTE(TRANSNUM)::"00":
RAW(ROUTE,LENGTH(ROUTE))::FF::"0003":WORD(REMOTE):WORD(COUNT)
ON RECEIVE PORT 1  WORD(REPLYLEN)::11::BYTE(TRANSNUM):RAW(ROUTE,4):
"FF::"8603":WORD((REMOTE)):RAW(REPLYDATA,REPLYLEN-4) GOTO <variable>

PPP Mode allows the CUCM to use the serial port for TCP/IP communication using the PPP protocol.

SET SOCKET <socket> NAGLE <const>
The Set Socket Nagle statement controls how data is sent out a TCP/IP connection. In a socket with NAGLE OFF, every TRANSMIT SOCKET command will create its own Ethernet packet. In a socket with NAGLE ON (The default state), data sent out the socket is buffered as necessary by the CUCM, which results in larger packets and better throughput, especially for applications such as a Telnet server or a WWW server.

SET PORT x MULTIDROP <const>
The SET MULTIDROP statement controls the operation of the port’s transmitter. With MULTIDROP TRUE, the transmitter is only on while transmitting. With MULTIDROP FALSE, the transmitter is always on.

SET PORT x RTS <const>
The SET RTS statement sets the operation of the RTS pin on the RS-232 port. Possible values are
RTS ON - Forces RTS on continuously
RTS OFF - Forces RTS off continuously
RTS AUTO - Allows RTS to behave in normal Push-to-Talk operation

SET PORT x DATA <const>
The SET DATA statement sets the number of data bits for the operation of the port. Valid range is 5,6,7, or 8 bits. Example: SET PORT 1 DATA 8

SET PORT x PARITY <const>
The SET PARITY statement determines the parity of the port. Valid entries are EVEN, ODD, or NONE. Example: SET PORT 1 PARITY EVEN

SET PORT x PPPUSERNAME <string const|string variable>
The SET PPPUSERNAME statement determines username for the PPP connection between the CUCM and the PPP client or server.

SET PORT x PPPPASSWORD <string const|string variable>
The SET PORT x PPPPASSWORD statement determines password for the PPP connection be-
SET PORT x PPPHANGUP

The SET PORT x PPPHANGUP statement causes a graceful disconnect between the PPP connection of the CUCM and the client/server.

SET PORT x STOP <const>

The SET STOP statement determines the number of stop bits for the port. Valid entries are 1 or 2. Example: SET PORT 2 STOP 2

SET (bit)

SET <variable>.<const> or SET <variable>.(<expr>)

The SET statement sets a single bit of a variable to ONE. The bit number <const> or <expr> must evaluate within the range of 1-16 for OUTPUT registers, 0-7 for bytes, 0-15 for words, and 0-31 for long variables. To clear a single bit of a register to be set to one use the CLEAR statement.

SOCKETSTATE

ON SOCKETSTATE (<socket>).<const> GOTO <label>
ON SOCKETSTATE (<socket>).<const> RETURN
IF SOCKETSTATE (<socket>).<const> THEN <expression>

The SOCKETSTATE statement allows the Application to make decisions based on the status of a socket that was initiated by a CONNECT statement. Status bits are set for the SOCKETSTATE of each declared socket. Bit 15 indicates when a socket is open. Bit 14 indicates that the socket is listening. These are the most useful bits.

STOP

The STOP statement causes the CUCM program to halt upon its execution. The program may be restarted by clearing and then setting the command bit for the program.

STOP (BITS)

See SET STOP on page 35.

SWITCH...CASE...ENDSWITCH

SWITCH CASE<expr><statement(s)> [CASE <expr> <statement(s)>] ENDSWITCH

The SWITCH...CASE...ENDSWITCH construct allows many mutually exclusive conditional statements or routines to be written without nesting a lot of IF...ELSE...ENDIF statements. Only one of the CASEs contained within the SWITCH...ENDSWITCH construct will be executed. For example:

SWITCH
CASE X=2
    Y = 2 * Y  {Will execute only if X = 2}
CASE X < 5
    Y = X * 5  {Will execute only if X < 5, but not if X = 2}
CASE Y > 10  {Logical expressions can operate on different variables}
    Y = 0
CASE TRUE  {Comparable to default: in C}
    Y = 99
    X = 0  {These will execute only if all other CASEs fail to match}
ENDSWITCH
Program execution will continue with the instruction immediately after the ENDSWITCH statement, whether any CASE matches or not.

**TOGGLE**

TOGGLE <variable>.<const> or TOGGLE <variable>.(<expr>)

The TOGGLE statement changes the state of a single bit of a variable. The bit number <const> or <expr> must evaluate within the range of 1-16 for OUTPUT registers, 0-7 for bytes, 0-15 for words, and 0-31 for long variables.

**TOGGLE LIGHT**

TOGGLE LIGHT <expr>

The TOGGLE LIGHT statement is used to change the state of the 10 indicator lights for the CUCM. See also the SET LIGHT command on page 33.

**TRANSMIT**

TRANSMIT PORT x <message description>

TRANSMIT SOCKET s <message description>

The TRANSMIT statement allows serial (or Ethernet) communication to be emitted from the port. The exact string evaluated from the <message description> will be emitted.

**WAIT**

The WAIT statement follows a group of ON RECEIVE, ON CHANGE, ON <expression>, and ON TIMEOUT statements. The WAIT statement causes a loop to occur until one of the ON RECEIVE, ON CHANGE, or ON TIMEOUT conditions has occurred. Program flow will be directed by the ON RECEIVE, CHANGE, <expression>, or TIMEOUT statement.

**WHILE...WEND**

WHILE <logical>

program statements

WEND

The WHILE statement starts a loop based upon the evaluation of the <logical> condition. The loop will only be performed as long as the <logical> is TRUE. When the <logical> is FALSE, program execution jumps to the statement following the WEND.

**WRITE FILE**

WRITE FILE <file number> OFFSET <offset value> <variable,variable,...>

The WRITE FILE statement allows a CUCM program to write memory from the user memory area to memory in the 6x file areas of the CUCM.

The <file number> is an expression which evaluates a number in Table 4-5.
The `<offset>` is an expression which evaluates to the byte location for the start of the read.

*NOTE: CUCM-SE RAM block 1 at file 768 is only 16K bytes and block 2 does not exist. Attempting to access these RAM areas will result in a runtime error.

### Table 4-5  CUCM Internal File List

The CUCM language includes a variety of commonly used functions to facilitate message generation and reception, and other program flow areas.

Checksum Functions

CRC

Form: CRC(<expr>,<expr>,<expr>)

The CRC function calculates the Cyclical Redundancy Check (CCITT standard) upon a message. The first <expr> is the starting index. This value is number of the character in the message where the CRC16 is to start. The second <expr> is the ending index, usually the $ or $-1 location. The final <expr> is the initial value for the checksum, usually a 0 or -1.

CRC16

Form: CRC16(<expr>,<expr>,<expr>)

The CRC16 function calculates the Cyclical Redundancy Check upon a message. The first <expr> is the starting index. This value is number of the character in the message where the CRC16 is to start. The second <expr> is the ending index, usually the $ or $-1 location. The final <expr> is the initial value for the checksum, usually a 0 or -1.

The CRC16 is a variation of the CCITT standard CRC and is sometimes called a CRC. The MODBUS RTU protocol uses the CRC16.

CRCAB

Form: CRCAB(<expr>,<expr>,<expr>)

The CRCAB function calculates the CRC16 Check upon a message while leaving out the $-2 character. The first <expr> is the starting index. This value is number of the character in the message where the CRC16 is to start. The second <expr> is the ending index, usually the $ location. The final <expr> is the initial value for the checksum, usually a 0.

The CRCAB is a variation of the CRC16 customized for use with the Allen-Bradley protocols.

CRCBOB

Form: CRCBOB(<expr>,<expr>,<expr>)
The CRCBOB function calculates the CRC16 Check upon a message while leaving out the $-2 character. The first <expr> is the starting index. This value is the number of the character in the message where the CRC16 is to start. The second <expr> is the ending index, usually the $ location. The final <expr> is the initial value for the checksum, usually a -1.

The CRCAB is a variation of the CRC16 customized for use with BinMaster Smartbob II’s.

**CRCAB**

*Form: CRCDNP(<expr>,<expr>,<expr>)*

The CRCDNP function calculates the CRC16 Check upon a message while leaving out the $-1 character. The first <expr> is the starting index. This value is the number of the character in the message where the CRC16 is to start. The second <expr> is the ending index, usually the $ location. The final <expr> is the initial value for the checksum, usually a 0.

The CRCDNP is a variation of the CRC16 customized for use with the DNP 3.00 protocol.

**LRC**

*Form: LRC(<expr>,<expr>,<expr>)*

The LRC function calculates the Longitudinal Redundancy Check upon a message. The first <expr> is the starting index. This value is the number of the character in the message where the LRC is to start. The second <expr> is the ending index, usually the $ or $-1 location. The final <expr> is the initial value for the checksum, usually a 0 or -1.

The LRC operates upon each byte of the message and the result of the function is a byte.

**LRCW**

*Form: LRCW(<expr>,<expr>,<expr>)*

The LRCW function calculates the Longitudinal Redundancy Check upon a message. The first <expr> is the starting index. This value is the number of the character in the message where the LRCW is to start. The second <expr> is the ending index, usually the $ or $-1 location. The final <expr> is the initial value for the checksum, usually a 0 or -1.

The LRCW operates upon each word of the message and the result of the function is a word.

**SUM**

*Form: SUM(<expr>,<expr>,<expr>)*

The SUM function calculates the straight hex sum of a message. The first <expr> is the starting index. This value is the number of the character in the message where the SUM is to start. The second <expr> is the ending index, usually the $ or $-1 location. The final <expr> is the initial value for the checksum, usually a 0 or -1.

The SUM function operates upon each byte of the message and returns a byte.

**SUMW**

*Form: SUMW(<expr>,<expr>,<expr>)*

The SUMW function calculates the straight hex sum of a message. The first <expr> is the starting index. This value is the number of the character in the message where the SUMW is to start. The second <expr> is the ending index, usually the $ or $-1 location. The final <expr> is the initial value for the checksum, usually a 0 or -1.

The SUMW function operates upon each word of the message and returns a word.
Message Description Functions

**BCD - Binary Coded Decimal conversion**

*Usual Format:* BCD(Register location, byte count)  
or BCD(Register location, VARIABLE)  
or BCD(Register location, VARIABLE, Register location)

*Valid characters:* hexadecimal 00 through 09, 10 through 19 ... 90 through 99.

*Transmitting:* Converts an expression into its decimal representation, breaks the decimal number into pairs of digits and then translates each pair of digits into its BCD character.

TRANSMIT format: BCD(<expr>,<expr>)

*Receiving:* Converts BCD characters into pairs of decimal digits, assembles the pairs into a 16 bit decimal number and then compares the number to an expression or places the number into an CUCM register.

ON RECEIVE formats: BCD(<variable>,<expr>) or BCD((<expr>),<expr>)

Note: The CUCM port must be set for 8 bit for BCD to work correctly.

**BYTE - Single (lower) byte conversion**

*Usual Format:* BYTE(Register location)

*Valid characters:* hexadecimal 00 through FF

*Transmitting:* Converts an expression into its hexadecimal representation and transmits the lower 8 bits as a hexadecimal character.

TRANSMIT format: BYTE(<expr>)

*Receiving:* Interprets hexadecimal characters as 8-bit hexadecimal numbers and then compares the numbers to an expression or places the numbers into the lower byte of CUCM registers and zeros the upper byte of these registers.

ON RECEIVE formats: BYTE(<variable>) or BYTE((<expr>))

Note: If the CUCM port is set to 7 bit then bit 8 will always be zero.

**DEC - Decimal conversion**

*Usual Format:* DEC(Register location, byte count)  
or DEC(Register location, VARIABLE)  
or DEC(Register location, VARIABLE, Register location)

*Valid characters:* ASCII + (plus sign), - (minus sign) and 0 through 9

*Transmitting:* Converts an expression into its signed decimal representation, breaks the signed decimal number into its sign and its digits and then translates each digit into its ASCII character.

TRANSMIT format: DEC(<expr>,<expr>)

After the significant digits the CUCM pads the front of the string with ASCII zeros. Does not transmit the plus (+) sign for positive numbers but does transmit a minus sign (-) on negative numbers.

*Receiving:* Converts ASCII characters into decimal digits with a sign, assembles the sign and digits into a 16 bit decimal number and then compares the number to an expression or places the number into an CUCM register.

ON RECEIVE formats: DEC(<variable>,<expr>) or DEC((<expr>),<expr>)

Total number of registers that can be affected: 1

Positive numbers can have a plus (+) sign preceding them but it is not required. Negative numbers must have a minus (-) sign preceding them.
**HEX - Hexadecimal conversion**

*Usual Format:*  
- HEX(Register location, byte count)
- or HEX(Register location, VARIABLE)
- or HEX(Register location, VARIABLE, Register location)

*Valid characters:* ASCII 0 through 9 and A through F

*Transmitting:* Converts an expression into its hexadecimal representation, breaks the hexadecimal number into its digits and then translates each hex digit into its ASCII character.

TRANSMIT format: HEX(<expr>,<expr>)

Maximum number of characters that can be sent:

*Receiving:* Translates ASCII characters into hexadecimal digits, assembles the digits into 16 bit hex numbers and then compares the numbers to an expression or places the numbers into CUCM registers.

ON RECEIVE formats: HEX(<variable>,<expr>) or HEX((<expr>),<expr>)

Total number of registers that can be affected: 16 (64 characters)

**HEXLC - Lower Case Hexadecimal conversion**

*Usual Format:*  
- HEXLC(Register location, byte count)
- or HEXLC(Register location, VARIABLE)
- or HEXLC(Register location, VARIABLE, Register location)

*Valid characters:* ASCII 0 through 9 and a through f

*Transmitting:* Converts an expression into its hexadecimal representation, breaks the hexadecimal number into its digits and then translates each hex digit into its ASCII character. Functions the same as HEX but accepts lower case characters a through f.

TRANSMIT format: HEXLC(<expr>,<expr>)

Maximum number of characters that can be sent: 4

*Receiving:* Translates ASCII characters into hexadecimal digits, assembles the digits into 16 bit hex numbers and then compares the numbers to an expression or places the numbers into CUCM registers. Transmits the hex alpha characters as lower case a through f.

ON RECEIVE formats: HEXLC(<variable>,<expr>) or HEXLC((<expr>),<expr>)

Total number of registers that can be affected: 1 (4 characters)

**IDEC conversion**

*Usual Format:*  
- IDEC(Register location, byte count)
- or IDEC(Register location, VARIABLE)
- or IDEC(Register location, VARIABLE, Register location)

*Valid characters:* ASCII 0 through 9 and : ; < = > ?

*Transmitting:* Converts an expression into its hexadecimal representation, breaks the hexadecimal number into its digits and then translates each hex digit into its pseudo-ASCII character. In pseudo-ASCII, hex digits 0 through 9 are there normal ASCII characters while hex digits A through F are replaced by the hex characters 3A through 3F which are the ASCII characters : ; < = > and ?.

TRANSMIT format: IDEC(<expr>,<expr>)

*Receiving:* Converts pseudo-ASCII characters into hexadecimal digits, assembles the digits into 16 bit hexadecimal numbers and then compares the numbers to an expression or places the numbers into CUCM registers.

ON RECEIVE formats: IDEC(<variable>,<expr>) or IDEC((<expr>),<expr>)
Note: This is the format that the IDEC processors and other devices use to pass register values. If communicating to an IDEC processor, a Square D Model 50 or Micro-1, or any other devices that use this pseudo-ASCII protocol this is a useful function.

**LONG**

*Usual Format:* LONG(Variable name)

*Valid characters:* hexadecimal 00 through FF

**Transmitting:** Converts an expression into its 32-bit hexadecimal representation, translates the 32-bit number into four 8-bit hexadecimal numbers and transmits the bytes in order of descending significance. If the variable VAR of type long contains 0x12345678, the four bytes would be transmitted: x12, x34, x56, x78.

**TRANSMIT format:** LONG(<expr>)

**Receiving:** Interprets four hexadecimal characters as four 8-bit hexadecimal numbers, assembles the four 8-bit numbers into a 32-bit number, first number the high byte, the second number in the second most significant byte, and the fourth number the low byte, and then compares the number to an expression or places the number into an CUCM variable.

**ON RECEIVE formats:** LONG(<variable>) or LONG((<expr>))

**OCT - Octal conversion**

*Usual Format:* OCT(Register location, byte count)

*Valid characters:* ASCII 0 through 7

**Transmitting:** Converts an expression into its octal representation, breaks the octal number into its digits and then translates each digit into its ASCII character.

**TRANSMIT format:** OCT(<expr>,<expr>)

**Receiving:** Converts ASCII characters into octal representation.

**ON RECEIVE formats:** OCT(<variable>,<expr>) or OCT((<expr>),<expr>)

**RAW - Raw register conversion**

*Usual Format:* RAW(Register location, byte count)

*Valid characters:* hexadecimal 00 through FF

**Transmitting:** Converts registers into their hexadecimal representation and translates each 16-bit hexadecimal number into a pair of 8-bit hexadecimal characters.

**TRANSMIT format:** RAW(<variable>,<expr>)

**Receiving:** Interprets hexadecimal characters as 8-bit hexadecimal numbers, assembles each pair of 8-bit numbers into a 16-bit hexadecimal number, high byte then low byte, and then compares the numbers to an expression or places the numbers into CUCM registers.

**ON RECEIVE formats:** RAW(<variable>,<expr>) or RAW((<expr>),<expr>)

Note: If the CUCM port is set to 7 bit then bit 8 and bit 16 will always be 0. RAW is an expanded version of SY/MAX packed ASCII and can be used to transmit and receive packed ASCII characters as well as 8-bit characters.

**RWORD**

*Usual Format:* RWORD(Register location)
Valid characters: hexadecimal 00 through FF

Transmitting: Converts an expression into its 16-bit hexadecimal representation, translates the 16-bit number into a pair of 8-bit hexadecimal numbers and transmits the lower eight bits and then the upper 8 bits as hexadecimal characters.

TRANSMIT format: RWORD(<expr>)

Receiving: Interprets two hexadecimal characters as two 8-bit hexadecimal numbers, assembles the two 8-bit numbers into a 16-bit number, first number low byte and second number high byte, and then compares the number to an expression or places the number into an CUCM register.

ON RECEIVE formats: RWORD(<variable>) or RWORD((<expr>))

Note: Like WORD but in the reverse order, low byte then high byte.

TON - Translate on

The commands TON and TOFF work with the TRANSLATE command. The TRANSLATE command defines a string that is to be translated into another string. This is used when a character has reserved meaning but could also be used in the translation of data. Up to 8 TRANSLATE strings can be contained in an CUCM program.

An example: the escape character (hex 1B) could be used to interrupt a transmission but hex 1B might also be valid data. When the remote process wants to interrupt transmission it sends a single hex 1B. But when the remote process wants to send data containing hex 1B it sends 1B1B and the CUCM is responsible for interpreting two hex 1Bs as a single 1B instead of as an escape. In this case the translate command would be:

TRANSLATE 1: "\1B\1B" = "\1B"

and the command for receiving data that might contain a hex 1B:

ON RECEIVE TON(1):RAW(STRINGVAR,15):TOFF(1)

The TON command turns on translation during an ON RECEIVE or TRANSMIT. The format for turning translation on is TON(<expr>) where <expr> is the translation number and must evaluate to be between 1 and 8. The TON is usually followed by a TOFF.

TOFF - Translate off

The TOFF command turns off translation during an ON RECEIVE or TRANSMIT. The format for turning translation off is TOFF(<expr>) where <expr> is the translation number and must evaluate to be between 1 and 8.

UNS - Unsigned decimal conversion

Usual Format: UNS(Register location, byte count)

or UNS(Register location, VARIABLE)

or UNS(Register location, VARIABLE, Register location)

Valid characters: ASCII 0 through 9

Transmitting: Converts an expression into its unsigned decimal representation, breaks the unsigned decimal number into its digits and then translates each digit into its ASCII character.

TRANSMIT format: UNS(<expr>,<expr>)

Receiving: Converts ASCII characters into decimal digits, assembles the digits into a 16 bit unsigned decimal number and then compares the number to an expression or places the number into an CUCM register.

ON RECEIVE formats: UNS(<variable>,<expr>) or UNS((<expr>),<expr>)

Total number of registers that can be affected: 1
WORD

*Usual Format:* \( \text{WORD(\text{Register location})} \)

*Valid characters:* hexadecimal 00 through FF

*Transmitting:* Converts an expression into its 16-bit hexadecimal representation, translates the 16-bit number into a pair of 8-bit hexadecimal numbers and transmits the upper eight bits and then the lower 8 bits as hexadecimal characters.

**TRANSMIT format:** \( \text{WORD(<expr>)} \)

*Receiving:* Interprets two hexadecimal characters as two 8-bit hexadecimal numbers, assembles the two 8-bit numbers into a 16-bit number, first number the high byte and second number the low byte, and then compares the number to an expression or places the number into an CUCM register.

**ON RECEIVE formats:** \( \text{WORD(<variable>)} \) or \( \text{WORD((<expr>))} \)

Note: Like RWORD but always high byte then low byte. Also like \( \text{RAW(<variable>,2)} \).

### Other Functions

**APPLICATION**

The APPLICATION internal variable returns a value of 1 or 2, indicating which application area the program is running in. A program which is loaded into application area 2 of a CUCM will read this variable as 2.

**CHANGED**

*Format:* \( \text{CHANGED(<variable>)} \) or \( \text{CHANGED(<variable> & <expr>)} \)

The CHANGED function provides a boolean result dependent upon whether the evaluated register or mask of the register has been altered from the last operation of this function. The first occurrence of the CHANGED function will result in a FALSE regardless of the state of the evaluated register.

The CHANGED function is used in any place referred to as \( \text{<logical>} \), such as:

\[
\text{IF CHANGED(OUTPUT[56]) THEN GOTO reply}
\]

The CHANGED function is similar to the ON CHANGE statement, but the CHANGED function allows program execution to continue running instead of pausing to wait for the change to occur.

**MAX**

*Format:* \( \text{MAX(<expr>,<expr>)} \)

The MAX function provides a result of the \( <\text{expr}> \) which evaluates to the larger of the two expressions.

**MIN**

*Format:* \( \text{MIN(<expr>,<expr>)} \)

The MIN function provides a result of the \( <\text{expr}> \) which evaluates to the smaller of the two expressions.

**SWAP**

*Format:* \( \text{SWAP(<expr>)} \)

The SWAP function reverses the byte order of the result of the \( <\text{expr}> \). If \( \text{OUTPUT[4]} = x\text{ABCD} \) then \( \text{SWAP(OUTPUT[4])} \) would bring the result \( x\text{CDAB} \).
**THREAD**

The THREAD variable returns a value for the thread number where the variable is called. Valid results are 1-8 inclusive.

**RTS**

RTS is a variable which may be used to control the state of the Request to Send line for a CUCM port. SET PORT 1 RTS ON will assert the RTS line. SET PORT 2 RTS OFF will negate the RTS line. SET PORT 1 RTS AUTO will force RTS to be in "push-to-talk" mode.

**CTSx**

CTSx is a variable which gives the current state of Clear to Send on the CUCM port. CTS1 provides the state for port 1 while CTS2 is for port 2. IF CTSx = TRUE then CTS is asserted by the external device. If CTSx = FALSE then CTS is negated.
TRANSMIT message function with register references

In the following TRANSMIT examples the following initial conditions are assumed:

<table>
<thead>
<tr>
<th>CUCM Register</th>
<th>Decimal</th>
<th>Signed Decimal</th>
<th>Hex</th>
<th>Octal</th>
<th>Binary</th>
</tr>
</thead>
<tbody>
<tr>
<td>OUTPUT[23]</td>
<td>41394</td>
<td>24142</td>
<td>A1B2</td>
<td>120662</td>
<td>1010 0001 1011 0010</td>
</tr>
<tr>
<td>OUTPUT[24]</td>
<td>20318</td>
<td>20318</td>
<td>4F5E</td>
<td>47536</td>
<td>0100 1111 0101 1110</td>
</tr>
</tbody>
</table>

**TRANSMIT HEX**

Command: TRANSMIT HEX(OUTPUT[23],4)
ASCII Characters transmitted: A1B2
Decimal values: 65 49 66 50
Hex values: 41 31 42 32

Command: TRANSMIT HEX(OUTPUT[23],2)
ASCII Characters transmitted: B2
Decimal values: 66 50
Hex values: 42 32

Command: TRANSMIT HEX(OUTPUT[23],8)
ASCII Characters transmitted: 0000A1B2
Decimal values: 48 48 48 48 65 49 66 50
Hex values: 30 30 30 30 41 31 42 32

Command: TRANSMIT HEX(OUTPUT[23],VARIABLE)
ASCII Characters transmitted: A1B2
Decimal values: 65 49 66 50
Hex values: 41 31 42 32

Command: TRANSMIT HEX(OUTPUT[23],VARIABLE R[600])
ASCII Characters transmitted: A1B2
Decimal values: 65 49 66 50
Hex values: 41 31 42 32
OUTPUT[600] would then equal 4.

**TRANSMIT DEC**

Command: TRANSMIT DEC(OUTPUT[23],6)
ASCII Characters transmitted: -24142
Decimal values: 45 50 52 49 52 50
Hex values: 2D 32 34 31 34 32

Command: TRANSMIT DEC(OUTPUT[23],5)
ASCII Characters transmitted: 24142
Decimal values: 50 52 49 52 50
Hex values: 32 34 31 34 32

Command: TRANSMIT DEC(OUTPUT[23],12)
ASCII Characters transmitted: -0000024142
Decimal values: 45 48 48 48 48 48 50 49 52 50
Hex values: 2D 30 30 30 30 30 32 34 31 34 32

Command: TRANSMIT DEC(OUTPUT[23],VARIABLE)
ASCII Characters transmitted: -24142
Decimal values: 45 50 52 49 52 50
Hex values: 2D 32 34 31 34 32

Command: TRANSMIT HEX(OUTPUT[23],VARIABLE LENGTHVARIABLE)
ASCII Characters transmitted: -24142
Decimal values: 45 50 52 49 52 50
Hex values: 2D 32 34 31 34 32
R[600] would then equal 6.

**TRANSMIT UNS**

Command: TRANSMIT UNS(OUTPUT[23],5)
ASCII Characters transmitted: 41394
Decimal values: 52 49 51 57 52
Hex values: 34 31 33 39 34

Command: TRANSMIT UNS(OUTPUT[23],3)
ASCII Characters transmitted: 394
Decimal values: 51 57 52
Hex values: 33 39 34

Command: TRANSMIT UNS(OUTPUT[23],8)
ASCII Characters transmitted: 00041394
Decimal values: 48 48 48 48 49 51 57 52
Hex values: 30 30 30 34 31 33 39 34

Command: TRANSMIT UNS(OUTPUT[23],8)
ASCII Characters transmitted: 00041394
Decimal values: 48 48 48 48 49 51 57 52
Hex values: 30 30 30 34 31 33 39 34

**TRANSMIT OCT**

Command: TRANSMIT OCT(OUTPUT[23],6)
ASCII Characters transmitted: 120662
Decimal values: 49 50 48 54 54 50
Hex values: 31 32 30 36 36 32

Command: TRANSMIT OCT(OUTPUT[23],3)
ASCII Characters transmitted: 662
Decimal values: 54 54 50
Hex values: 36 36 32
Command: TRANSMIT OCT(OUTPUT[23], VARIABLE)
ASCII Characters transmitted: 120662
Decimal values: 49 50 48 54 54 50
Hex values: 31 32 30 36 36 32
Command: TRANSMIT OCT(OUTPUT[23], VARIABLE R[600])
ASCII Characters transmitted: 120662
Decimal values: 49 50 48 54 54 50
Hex values: 31 32 30 36 36 32
R[600] would then equal 6.

TRANSMIT BCD

Command: TRANSMIT BCD(OUTPUT[23],3)
ASCII Characters transmitted: {not ASCII characters}
Decimal values: 4 19 148
Hex values: 04 13 94
Command: TRANSMIT BCD(OUTPUT[23],1)
ASCII Characters transmitted: {not ASCII character}
Decimal values: 148
Hex values: 94
Command: TRANSMIT BCD(OUTPUT[23],5)
ASCII Characters transmitted: {not ASCII characters}
Decimal values: 0 0 4 19 148
Hex values: 00 00 04 13 94
Command: TRANSMIT BCD(OUTPUT[23], VARIABLE)
ASCII Characters transmitted: {not ASCII characters}
Decimal values: 4 19 148
Hex values: 04 13 94
Command: TRANSMIT BCD(OUTPUT[23], VARIABLE OUTPUT[600])
ASCII Characters transmitted: {not ASCII characters}
Decimal values: 4 19 148
Hex values: 04 13 94
OUTPUT[600] would then equal 3.

ON RECEIVE message functions with register references

In the following ON RECEIVE examples it assumed that a WAIT follows immediately after the ON RECEIVE command, there are no other ON RECEIVEs set up for the WAIT and the incoming string is the following group of ASCII characters:

D876543F

Before the WAIT is executed, the following initial conditions are present:

<table>
<thead>
<tr>
<th>CUCM Register</th>
<th>Hex</th>
<th>Unsigned</th>
<th>Decimal</th>
<th>Octal</th>
<th>Binary</th>
</tr>
</thead>
<tbody>
<tr>
<td>OUTPUT[23]</td>
<td>A1B2</td>
<td>41394</td>
<td>-24142</td>
<td>120662</td>
<td>1010 0001 1011 0010</td>
</tr>
<tr>
<td>OUTPUT[24]</td>
<td>03F5</td>
<td>1013</td>
<td>1013</td>
<td>1765</td>
<td>0000 0011 1111 0101</td>
</tr>
</tbody>
</table>

Several of the examples have remaining characters. The remaining characters will be received by the CUCM and buffered until the next ON RECEIVE is reached by the program. This is not good programming practice unless these characters are meant to be handled elsewhere in the program. If they are not handled correctly, ON RECEIVEs later in the program may give unexpected results.
ON RECEIVE HEX

Command: ON RECEIVE HEX(OUTPUT[23],4) RETURN

Results after WAIT:
Characters used: D876
Translated to: hex D876

<table>
<thead>
<tr>
<th>Hex</th>
<th>Unsigned decimal</th>
<th>Decimal</th>
<th>Binary</th>
</tr>
</thead>
<tbody>
<tr>
<td>Register 23</td>
<td>D876</td>
<td>55,414</td>
<td>-10,122</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>1101 1000 0111 0110</td>
</tr>
<tr>
<td>Register 24</td>
<td>03F5</td>
<td>1,013</td>
<td>1,013</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>0000 0011 1111 1001</td>
</tr>
</tbody>
</table>

Remaining characters: "543F"

Command: ON RECEIVE HEX(OUTPUT[23],8) RETURN

Results after WAIT:
Characters used: D876543F
Translated to: hex D876 and hex 543F

<table>
<thead>
<tr>
<th>Hex</th>
<th>Unsigned decimal</th>
<th>Decimal</th>
<th>Binary</th>
</tr>
</thead>
<tbody>
<tr>
<td>Register 23</td>
<td>D876</td>
<td>55,414</td>
<td>-10,122</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>1101 1000 0111 0110</td>
</tr>
<tr>
<td>Register 24</td>
<td>543F</td>
<td>21,567</td>
<td>21,567</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>1001 1000 0011 1111</td>
</tr>
</tbody>
</table>

Note: Every character is used by this HEX function. The string was meant for a statement similar to this one, in that it handles all of the characters.

Command: ON RECEIVE HEX(R[23],2) RETURN

Results after WAIT:
Characters used: D8
Translated to: hex D8

<table>
<thead>
<tr>
<th>Hex</th>
<th>Unsigned decimal</th>
<th>Decimal</th>
<th>Binary</th>
</tr>
</thead>
<tbody>
<tr>
<td>Register 23</td>
<td>00D8</td>
<td>216</td>
<td>216</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>0000 0000 1101 1000</td>
</tr>
<tr>
<td>Register 24</td>
<td>03F5</td>
<td>1,013</td>
<td>1,013</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>0000 0011 1111 0101</td>
</tr>
</tbody>
</table>

Remaining characters: "76543F"

ON RECEIVE DEC

Command: ON RECEIVE DEC(OUTPUT[23],4) RETURN

Results after WAIT:
Characters used: D8765
Translated to: decimal 8,765

<table>
<thead>
<tr>
<th>Hex</th>
<th>Unsigned decimal</th>
<th>Decimal</th>
<th>Binary</th>
</tr>
</thead>
<tbody>
<tr>
<td>Register 23</td>
<td>223D</td>
<td>8,765</td>
<td>8,765</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>0010 0010 0011 1101</td>

<td>1,013</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>0000 0011 1111 0101</td>
</tr>
</tbody>
</table>

Note: The first received character "D" is ignored by the DEC() function. This is all right but if a D is always the leading character then a program statement like ON RECEIVE "D":DEC(OUTPUT[23],4) may be better.
Remaining characters: "43F"

Command: ON RECEIVE DEC(OUTPUT[23],5) RETURN

Results after WAIT:
Characters used: D87654
Translated to: decimal $87,654 \% 65,536 = 22,118$

<table>
<thead>
<tr>
<th>Hex</th>
<th>Unsigned decimal</th>
<th>Decimal</th>
<th>Binary</th>
</tr>
</thead>
<tbody>
<tr>
<td>Register 23</td>
<td>5666</td>
<td>22,118</td>
<td>0101 0110 0110 0110</td>
</tr>
<tr>
<td>Register 24</td>
<td>03F5</td>
<td>1,013</td>
<td>0000 0011 1111 0101</td>
</tr>
</tbody>
</table>

Note: The first "D" is ignored similar to the previous ON RECEIVE..
Remaining characters: "3F"

Command: ON RECEIVE DEC(OUTPUT[23],2) RETURN

Results after WAIT:
Characters used: D87
Translated to: decimal 87

<table>
<thead>
<tr>
<th>Hex</th>
<th>Unsigned decimal</th>
<th>Decimal</th>
<th>Binary</th>
</tr>
</thead>
<tbody>
<tr>
<td>Register 23</td>
<td>0057</td>
<td>87</td>
<td>0000 0000 0101 0111</td>
</tr>
<tr>
<td>Register 24</td>
<td>03F5</td>
<td>1,013</td>
<td>0000 0011 1111 0101</td>
</tr>
</tbody>
</table>

Note: The "D" is ignored as above.
Remaining characters: "6543F"

**ON RECEIVE UNS**

Command: ON RECEIVE UNS(OUTPUT[23],4) RETURN

Results after WAIT:
Characters used: D8765
Translated to: unsigned decimal 8,765

<table>
<thead>
<tr>
<th>Hex</th>
<th>Unsigned decimal</th>
<th>Decimal</th>
<th>Binary</th>
</tr>
</thead>
<tbody>
<tr>
<td>Register 23</td>
<td>223D</td>
<td>8,765</td>
<td>0010 0010 0011 1101</td>
</tr>
<tr>
<td>Register 24</td>
<td>03F5</td>
<td>1,013</td>
<td>0000 0011 1111 0101</td>
</tr>
</tbody>
</table>

Note: the first received character "D" is ignored by the UNS() function.
Remaining characters: "43F"

Command: ON RECEIVE UNS(OUTPUT[23],5) RETURN

Results after WAIT:
Characters used: D87654
Translated to: unsigned decimal $87,654 \% 65,536 = 22,118$

<table>
<thead>
<tr>
<th>Hex</th>
<th>Unsigned decimal</th>
<th>Decimal</th>
<th>Binary</th>
</tr>
</thead>
<tbody>
<tr>
<td>Register 23</td>
<td>5666</td>
<td>22,118</td>
<td>0101 0110 0110 0110</td>
</tr>
<tr>
<td>Register 24</td>
<td>03F5</td>
<td>1,013</td>
<td>0000 0011 1111 0101</td>
</tr>
</tbody>
</table>
Note: The "D" is ignored. The next five characters "87654" do not make a valid unsigned decimal number and so the UNS() function takes the incoming number and does a modulus 65,536. In this case the result is 22,118.

Remaining characters: "3F"

Command: ON RECEIVE UNS(OUTPUT[23],2) RETURN

Results after WAIT:
Characters used: D87
Translated to: decimal 87

Note: The "D" is ignored.
Remaining characters: "6543F"

**ON RECEIVE OCT**

Command: ON RECEIVE OCT(R[23],5) RETURN

Results after WAIT:
Characters used: D876543
Translated to: octal 76543

<table>
<thead>
<tr>
<th></th>
<th>Hex</th>
<th>Unsigned decimal</th>
<th>Decimal</th>
<th>Binary</th>
<th>Octal</th>
</tr>
</thead>
<tbody>
<tr>
<td>Register 23</td>
<td>7D63</td>
<td>32,099</td>
<td>32,099</td>
<td>0111 1101 0110 0011</td>
<td>076543</td>
</tr>
<tr>
<td>Register 24</td>
<td>03F5</td>
<td>1,013</td>
<td>1,013</td>
<td>0000 0011 1111 0101</td>
<td>001765</td>
</tr>
</tbody>
</table>

Note: The first two received characters "D8" are not octal digits and are ignored by the OCT() function.
Remaining characters: "F"

Command: ON RECEIVE OCT(OUTPUT[23],2) RETURN

Results after WAIT:
Characters used: D876
Translated to: octal 76

<table>
<thead>
<tr>
<th></th>
<th>Hex</th>
<th>Unsigned decimal</th>
<th>Decimal</th>
<th>Binary</th>
<th>Octal</th>
</tr>
</thead>
<tbody>
<tr>
<td>Register 23</td>
<td>003E</td>
<td>62</td>
<td>62</td>
<td>0000 0000 0011 1110</td>
<td>000076</td>
</tr>
<tr>
<td>Register 24</td>
<td>03F5</td>
<td>1,013</td>
<td>1,013</td>
<td>0000 0011 1111 0101</td>
<td>001765</td>
</tr>
</tbody>
</table>

Note: The "D" and the "8" are ignored.
Remaining characters: "543F"

Command: ON RECEIVE OCT(OUTPUT[23],6) RETURN

Results after WAIT:
Characters used: D876543F
Translated to: nothing
Note: Since "D", "8" and "F" are not valid octal characters they are lost by the OCT command. Between the "8" and the "F" the octal characters "76543" were received, which is only 5 characters instead of the 6 required by this ON RECEIVE. Since the next character "F" was not an octal character the previous 5 characters are ignored as not matching 6 octal characters in a row. So, not enough octal characters have been transmitted for this command. If this command is used without an ON TIMEOUT then the program will wait until 6 octal characters in a row are sent before completing this ON RECEIVE. Also note that register 23 has not yet changed.

Remainig characters: None - waiting for 6 octal characters in a row

**ON RECEIVE BCD**

Command: ON RECEIVE BCD(OUTPUT[23],2) RETURN

*Results after WAIT:*

Characters used: D8 (hexadecimal 44 and 38)  
Translated to: decimal 4,438

<table>
<thead>
<tr>
<th>Hex</th>
<th>Unsigned decimal</th>
<th>Decimal</th>
<th>Binary</th>
</tr>
</thead>
<tbody>
<tr>
<td>Register 23</td>
<td>A1B2</td>
<td>41,394</td>
<td>-24,142</td>
</tr>
<tr>
<td>Register 24</td>
<td>03F5</td>
<td>1,013</td>
<td>1,013</td>
</tr>
</tbody>
</table>

Note: The first two received characters "D" and "8" are used by the BCD() function. The "D" is a hex character 44 and the "8" is a hex character 38 and so the unsigned decimal value is 4438.

Remaining characters: "76543F"

Command: ON RECEIVE BCD(OUTPUT[23],4) RETURN

*Results after WAIT:*

Characters used: D876 (hexadecimal 44 38 37 36)  
Translated to: decimal 44,383,736 converted to 15,864

<table>
<thead>
<tr>
<th>Hex</th>
<th>Unsigned decimal</th>
<th>Decimal</th>
<th>Binary</th>
</tr>
</thead>
<tbody>
<tr>
<td>Register 23</td>
<td>1156</td>
<td>4,438</td>
<td>4,438</td>
</tr>
<tr>
<td>Register 24</td>
<td>03F5</td>
<td>1,013</td>
<td>1,013</td>
</tr>
</tbody>
</table>

Note: Both register 23  were changed

Remaining characters: None

**ON RECEIVE RAW**

Command: ON RECEIVE RAW(OUTPUT[23],2) RETURN

*Results after WAIT:*

Characters used: D8 (hexadecimal 44 38)
Translated to: hexadecimal 4438

<table>
<thead>
<tr>
<th></th>
<th>Hex</th>
<th>Unsigned decimal</th>
<th>Decimal</th>
<th>Binary</th>
</tr>
</thead>
<tbody>
<tr>
<td>Register 23</td>
<td>4438</td>
<td>17,464</td>
<td>17,464</td>
<td>0100 0100 0011 1000</td>
</tr>
<tr>
<td>Register 24</td>
<td>03F5</td>
<td>1,013</td>
<td>1,013</td>
<td>0000 0011 1111 0101</td>
</tr>
</tbody>
</table>

Note: The "D" is a hex 44 and the "8" is a hex 38 so register 23 is now 4438
Remaining characters: "76543F"

Command: ON RECEIVE RAW(OUTPUT[23],1) RETURN

Results after WAIT:
Characters used: D (hexadecimal 44)
Translated to: hexadecimal 4400

<table>
<thead>
<tr>
<th></th>
<th>Hex</th>
<th>Unsigned decimal</th>
<th>Decimal</th>
<th>Binary</th>
</tr>
</thead>
<tbody>
<tr>
<td>Register 23</td>
<td>4400</td>
<td>17,408</td>
<td>17,408</td>
<td>0100 0100 0000 0000</td>
</tr>
<tr>
<td>Register 24</td>
<td>03F5</td>
<td>1,013</td>
<td>1,013</td>
<td>0000 0011 1111 0101</td>
</tr>
</tbody>
</table>

Note: The RAW function places the first character into the upper bits of the register and zeros the rest of the bits.
Remaining characters: "876543F"

Command: ON RECEIVE RAW(OUTPUT[23],4) RETURN

Results after WAIT:
Characters used: D876 (hexadecimal 44 38 37 36)
Translated to: hexadecimal 4438 and 3736

<table>
<thead>
<tr>
<th></th>
<th>Hex</th>
<th>Unsigned decimal</th>
<th>Decimal</th>
<th>Binary</th>
</tr>
</thead>
<tbody>
<tr>
<td>Register 23</td>
<td>4438</td>
<td>17,464</td>
<td>17,464</td>
<td>0100 0100 0011 1000</td>
</tr>
<tr>
<td>Register 24</td>
<td>3736</td>
<td>14,134</td>
<td>14,134</td>
<td>0011 0111 0011 0110</td>
</tr>
</tbody>
</table>

Note: RAW changed both register 23 and 24
Characters remaining: "543F"

**ON RECEIVE BYTE**

Command: ON RECEIVE BYTE(OUTPUT[23]) RETURN

Results after WAIT:
Characters used: D (hexadecimal 44)
Translated to: hexadecimal 0044

<table>
<thead>
<tr>
<th></th>
<th>Hex</th>
<th>Unsigned decimal</th>
<th>Decimal</th>
<th>Binary</th>
</tr>
</thead>
<tbody>

</tr>
</tbody>
</table>

Note: Only OUTPUT[23] is changed.
Characters remaining: "76543F"
QCOMPILE.EXE

QCOMPILE.EXE is an MS-DOS compatible program for compiling the CUCM configuration text file into machine readable code. All CUCM configurations must be compiled before they can be downloaded into the CUCM. The downloading is done by a Windows compatible program QLOAD.EXE described in a later section of the manual.

The QCOMPILE command syntax is as follows:

Where filename refers to the text file containing the source code for the CUCM.

The .ext is an optional extension to the filename. If no extension is included then .QCM is assumed by the compiler.

Options can appear in any order. Additional options may be displayed by using -? as an option.

-O option

The -O option is for specifying an output file other than filename.qcc. If the -O option is not used then COMPILE will create the output file filename.qcc. If the -O option is used then COMPILE will create an output file named file2. If an extension is desired for file2 it needs to be added since no extension is assumed by the compiler.

-D option

The -D option is for specifying DEFINE macros at compile time. This is very useful for compiling one CUCM configuration file for more than 1 port of the same CUCM module. The macro portion of the -D option is the string inside of the CUCM configuration file that is to be found while string portion is macro’s replacement. It is equivalent to Find what: macro Change to: string in DOS EDIT.

If, in the configuration file AMAZING.QCM, the word Time has been used and Time needs to have a value of 50 then the DOS command to compile AMAZING with the Time replacement is:

QCOMPILE AMAZING -DTime=50

If the compile completes with no errors then the output file AMAZING.QCC will be created. If more than one DEFINE is needed at compile time then they can be added to the end of the COMPILE command as in:
The -L option

The -L option is for telling the compiler to also generate a 68000 source listing. The name of the DOS text file is file3. If an extension is desired for file3 it needs to be added since no extension is assumed by the compiler.

The 68000 source listing, file3, is a text file that can be read by your favorite text editor. If you have any questions about the way the compiler generates code for the CUCM then you can use the -L option. Most users will not have a use for this option.

The -S option

The -S option is for generating a list of the location of each declared variable. The variables are located in the 6x file areas of the CUCM. Application 1 variables are located in file 384. Application 2 variables are located in file 640.

The variable list is displayed as a table, sorted by the order that the variables were declared. The table has columns that show the variable’s byte address, register address, type, number of elements (if applicable), number of bytes, and what thread they were assigned to.

The -W option

The -W option disables warnings that indicate possible trouble but do not prohibit the program from successfully compiling. Mostly used for disabling the "Program is too large" warnings on large applications that use the optional large flash for application 2.

Compiler Errors

When the CUCM configuration file contains code that the compiler does not recognize, variables out of range, code that is too long or any other error then the compiler generates an error listing. This listing will have the compiler error number, the line number in the .CUCM file where the error occurred, a copy of the line in question, and a description of the error. The listing will also summarize the total number of errors detected.

The programmer can use this listing to correct problems in the CUCM configuration file. Since no object code is generated if an error occurs during the compile, all errors must be repaired before a valid object file can be made for downloading into the CUCM.

Debugging

For debugging purposes the user may want to store the error listing in a file in order to refer to it later. This can be accomplished with the output redirection feature of DOS. For example:

```
QCOMPILE <filename >error.lst
```

The text that normally would go to the screen will now appear in the text file error.lst.
QLOAD.EXE

The program QLOAD.EXE is a Windows program that will download compiled applications into a CUCM via Modbus serial or TCP/IP Ethernet.

Figure 8-1 Ethernet QLOAD
Figure 8-2 Serial QLOAD

Options:
- **Application 1** Loads Application into the first Application area.
- **Application 2** Loads Application into the second Application area.
- **Status Register** 3x Register for the status of the Application.
- **Run Pointer** 4x Register that points to the Status Register.
- **Auto Start** Enables Autostart for the Application.
- **Erase Flash** Erases Application area before writing new App.
- **Load File** Loads new Application into Application area.
- **Set Defaults** Sets all options to factory default.
- **Start Download** Begins file transfer to CUCM.
- **Cancel** Closes the QLOAD window.

Modbus TCP Options:
- **First Line** IP address of CUCM to be loaded.
- **TCP Port** Modbus TCP port for connecting to the CUCM.
- **Modbus Drop** Modbus drop of CUCM.

Modbus Serial Options:
- **First Line** COM: port of PC connected to the CUCM.
- **Baud** Baud rate of CUCM serial port.
- **Modbus Drop** Modbus drop of CUCM.
- **ASCII** Select to change from Modbus RTU to Modbus ASCII.
- **7/8 Bits** Select radio button for number of data bits.
- **Parity** Parity selection.

Example:

The file HELLO.qcc is a simple CUCM Application that interacts with Hyperterminal to produce messages on the PC’s screen based on what the user types in. This application is to be loaded into Application 1.

To load the file from COM1 of a PC with an MM1 serial cable to one of the serial ports on the CUCM-OE simply do the following:

1. Move the switches for Applications 1 and 2 to HALT.
2. Connect the MM1 to the PC’s COM1 port and one of the serial ports on the CUCM-OE.
3. In Windows, go to Start-->Programs-->Niobrara-->CUCM-->QLOAD.
4. Click the Browse... button, then browse to C:\Niobrara\Apps\CUCM\hello.qcc.
5 Make sure the Modbus Serial page is selected.
6 Keep the default settings, and click the Start Download button.

This will start loading the application and set it to automatically start on power cycles. HELLO.qcc is a relatively small Application and takes only a minute to download via Modbus RTU serial at 9600 baud. However, for larger Applications, it is advisable to set up the Ethernet port on the CUCM-OE for Modbus/TCP operation and then use the Ethernet port of the PC for the QLOAD. To set the IP parameters in the CUCM do the following:

1 Move the switches for Applications 1 and 2 to HALT.
2 Connect the MM1 to the PC’s com1 port and one of the serial ports on the CUCM-OE.
3 From the command line on the computer enter:
   
   `>zapreg32 com1:9600,e,8,1 255 -b`
   
   This will bring up a copy of zapreg32 in Modbus RTU mode to allow direct editing of the Holding registers in the CUCM.
4 Move to register 46 and enter the most significant portion of the IP address in the unsigned column. The remaining IP parameters are stored in registers 47 through 56. See the Table below:

<table>
<thead>
<tr>
<th>CUCM Output Register</th>

</tr>
</tbody>
</table>

5 Exit ZAPREG32 after entering the IP parameters by pressing ESC.
6 Verify the IP operation of the computer and CUCM-OE by using the PING utility. If it is successful the output from PING should look something like the following:
   
   `>ping 10.10.10.10`
   
   Pinging 10.10.10.10 with 32 bytes of data:
   Reply from 10.10.10.10: bytes=32 time=10ms TTL=128
   Reply from 10.10.10.10: bytes=32 time<10ms TTL=128
   Reply from 10.10.10.10: bytes=32 time=10ms TTL=128
   Reply from 10.10.10.10: bytes=32 time<10ms TTL=128
   If the ping fails then verify the IP operation of the PC, check that the CUCM’s LINK light is on, check the Ethernet cabling and hubs, etc.
7 Once the CUCM is responding to PINGS from the PC proceed to the QLOAD in the same manner as above, but with the Modbus TCP option selected.
8 Enter the IP address of the CUCM, keep the default settings, and click Start Download. This download will be much quicker than the serial download.

The NR&D BB-85 may be used to bring the RS-485 signal lines out to a removable Screw Terminal block. The BB-85 is a small DIN-rail mounted block which connects to the CUCM serial port with an included straight-through RJ-45 to RJ-45 cable (the NR&D MM0, or a Twisted Pair Ethernet patch cable may be used).

For 2-wire RS-485 applications, Rx+ and Tx+ must be tied together outside the CUCM, and Rx- and Tx- must also be tied together outside the CUCM.

Cabling required to configure a CUCM

Configuration files are downloaded from an MS-DOS personal computer into the CUCM. The factory default configuration for the module is that all ports not running a user program are Modbus RTU, 9600 baud, 8 data bits, EVEN parity, 1 stop bit which may be used for downloading user programs or for viewing and modifying CUCM registers. The correct cabling needs to be installed to connect the personal computer to a CUCM port.

**CUCM RS-232 to personal computer cabling**

A connection to the RS-232 port of the PC may be made to either of the RS-232 ports of the module.

CUCM RS-232 to 9-pin DTE

The Niobrara MM3 cable may be used to connect the CUCM RS-232 port to a 9-pin DCE device. This cable gives the CUCM a standard PC type 9-pin male connector. The MM3 may be used in conjunction with the MM1 to connect two Modicon type RJ45 serial ports together. The MM3 may be used with a Niobrara SC902 cable to connect a Modicon type RJ45 RS-232 serial port to a SY/MAX type RS-422 port.

Isolated Cabling to SY/Max Port

The Niobrara DDC2I Isolated RS-232<>RS-422/485 converter provides an optically isolated connection from the CUCM to a SY/Max pinout device. A Niobrara MM0 cable is used to connect the RS-232 port on the CUCM to the RJ45 port on the DDC2I. A Niobrara DC1 cable is used to connect the 9-pin RS-422 port on the DDC2I to the SY/Max device. The DIP switches on the DDC2I should be set for 4-Wire, Bias, and Termination. The CUCM will provide the power for the DDC2I.

The Niobrara MM3 and SC902 cables may also be used together to provide a non-isolated connection between the CUCM-S and a SY/Max port.

As new features and fixes are added to the CUCM, it may become necessary for the user to upgrade their firmware to take advantage of these changes. The CUCM’s operating firmware is stored in FLASH memory and may be downloaded through serial Port 1 using an RS-232 cable and a special program called FWLOAD32.EXE or over a Modbus or Modbus/TCP connection using QLOAD.

**QLOAD Operation**

QLOAD may be used to upgrade the firmware in the CUCM by loading a special version of the firmware that has been compiled as a .QCC. The new firmware must be qloaded into application 1 and set for automatic start. The RUN 1 switch must also be set to RUN. The QLOAD operation replaces the normal application in Application 1 with the new firmware. As the new firmware application begins to run, it takes over the CUCM hardware and upgrades itself. The upgrade process takes about 20 seconds and the CUCM is completely disabled during this time. After the completion of the upgrade, the CUCM reboots and runs the new firmware. Application 1 is now erased and the original application must be reloaded.

Using QLOAD to upgrade the firmware in the CUCM can have great advantages over FWLOAD32. It is possible to QLOAD new firmware over the Ethernet connection using Modbus/TCP and thus allow remote upgrades over a LAN, WAN, or Internet. QLOAD may also be used to upgrade firmware over a Modbus RTU serial connection which may be handy in modem applications. Moving the switch on the rear of the CUCM is not required so the entire operation may be accomplished remotely.

1. Make sure that the RUN1 switch is in RUN.
2. QLOAD the file qucmcntp1.qcc into application 1 just as a normal loading of application 1.
3. After the QLOAD is completed, wait approximately 20 seconds for the firmware upgrade to complete.
4. QLOAD the original Application 1 back into the unit and it is ready to operate.

Note: If at any point during this procedure the download fails, it will be necessary to reboot the CUCM before trying again.
**FWLOAD32 Operation**

Sometimes it may be necessary to use FWLOAD32 to upgrade the firmware in the CUCM. FWLOAD requires a direct serial connection to Port 1 of the CUCM and removal of power and changing of the switch on the back of the CUCM from RUN to LOAD. FWLOAD is faster than QLOAD over a serial connection and it is not necessary to reload application 1 when finished.

1. Remove the CUCM from the rack.
2. Locate the slide switch on the back of the module and move the switch to the LOAD (down) position.
3. Install the CUCM in the rack. The lights should flash the normal boot sequence and finish with the only the RUN and #3 lights on.
4. Connect the personal computer to Port 1 of the CUCM with an MM1 cable.
5. If the CUCM is an -O or a -OE model, put port 1’s selector switch in the RS-232 position.
6. Run the program FWLOAD32.EXE with the following parameters:
   ```
c:\qucm\fwload qucmtcp.fw1 com1:
   ```
   if using the PC’s com1 for the serial connection or substitute the appropriate COMx: port.
7. After the completion of the download, the program will end.
8. Remove the CUCM from the rack and move the slide switch back to RUN.
9. Install the CUCM in the rack and it should be ready for service. It may be necessary to download the Applications before returning the unit to service.

Note: If at any point during this procedure the download fails, it will be necessary to reboot the CUCM before trying again.

SET PORT <port number> STOP <const>

DEFINE <macro>=<replacement string> newline

CONSTANTS <const> in descriptions above

decimal numbers 12345
signed numbers -123
hexadecimal constant x12ab
reserved constants:
   EVEN
   ODD
   NONE

boolean constants:
   TRUE
   FALSE

EXPRESSIONS <NUMERIC expr> above

Operators:
   - unary negation
   ~ unary bitwise complement
   * multiplication
   / division
   % modulus
   + addition
   - subtraction
   << left shift
   >> right shift
   & bitwise AND
   | bitwise OR
   ^ bitwise XOR
   () parenthesis

Precedence:
   First, operands or sub expressions in parenthesis
   Then unary negation - or complement ~
   Then *, /, % left to right
   Then +, - left to right
   Then <<, >> left to right
   Then & left to right
   Then |, ^ left to right

Functions:
   CRC( <expr>,<expr>,<expr>) {only used in message descriptions}
   SUM( <expr>,<expr>,<expr>)
   SUMW(<expr>,<expr>,<expr>)
   LRC( <expr>,<expr>,<expr>)
   LRCW(<expr>,<expr>,<expr>)
   CRC16(<expr>,<expr>,<expr>)
   | | | +----- initial value usually 0 or -1
   | +------------- ending index
   +--------------- starting index
MIN(<expr>,<expr>)
MAX(<expr>,<expr>)
SWAP(<expr>) {reverses byte order of a word}

LOGICAL EXPRESSIONS <logical> above

Logical Operators:
  AND
  OR
  XOR
  NOT (unary)

Logical Functions:
  CHANGED(<variable>)
  CHANGED(<variable> & <expr>)
  <variable>.<const> {constant bit number 1..16}

Relational Operators:
  <  less than
  >  greater than
  <= less than or equal
  >= greater than or equal
  = equal
  <> not equal

ARITHMETIC VARIABLES
$ the current index in a message description

MESSAGE DESCRIPTIONS

Operator:
  : concatenation

Literal string:
  Enclosed in quotes.
  \xx where xx is two digit hex number can be used for non-printables
  " can be used to embed a quotation mark
  \ can be used to embed a \n
  \a - Bell, same as "\07", makes printers and terminals beep
  \b - Backspace, "\08", nondestructive backspace
  \f - Form feed, "\0c", top of form, clears some terminal screens
  \n - New line, "\0a"
  \r - Return, "\0d"
  \t - Tab, "\09", advances to tab stop
  \v - Vertical tab, "\0b", used by some printers with VFU

Unlike 'C', the CUCM compiler accepts the above sequences in upper or lower case. These are in addition to the original CUCM escape sequence:

\xx - where each x is 0..9, A..F
and last but not least: \? - where ? is any character encodes that character which is commonly used for: \ - literal slash or " - literal quote
The CUCM compiler does not recognize the BASIC style "" to represent "."

**Functions:**

- HEX(expr, expr)
- DEC(expr, expr)
- UNS(expr, expr)
- OCT(expr, expr)
- BCD(expr, expr)

  | width in characters
  | expression in TRANSMIT
  <variable> in ON RECEIVE to evaluate and place result in RXVARIABLE
  (expr) in ON RECEIVE to generate and match string

- RAW(variable, expr)

  | width in characters
  | expression in TRANSMIT
  <variable> in ON RECEIVE to evaluate and place result in RXVARIABLE
  (expr) in ON RECEIVE to generate and match string

- BYTE(expr)
- WORD(expr)
- RWORD(expr)

  | expression in transmit
  <variable> in ON RECEIVE to evaluate and place result in RXVARIABLE
  (expr) in ON RECEIVE to generate and match string

- TON(expr)
- TOFF(expr)

  | translation number 1..8

**CUCM RUN TIME ERROR CODES**

- 0 - Halted by clearing RUN bit
- 1 - Halted by STOP or RETURN statement
- 2 - Execution of invalid instruction (program corrupted, compiler bug)
- 3 - Division by zero
- 4 - No memory for ON CHANGE
- 5 - No memory for ON RECEIVE
- 6 - Illegal run time call (module firmware version doesn’t support compiler)
- 7 - Value out of bounds (register < 1 or > 2048, buffer index out of range,
  SET parameter bad, output/input too long (> 256),
  width specification < 0 or > 64)
- 8 - Checksum error in downloaded code

**CUCM Reserved Word List**

The following lists of words are reserved by the CUCM language. These words may not be used for define macro names or labels.

</table>
The register configuration of the CUCM is governed by its entry in the Traffic Cop description and characteristic file: GCNFTCOP.SYS. This file is typically located in the \MODSOFT\RUNTIME directory.

NOTE: Pay special notice to the warning about editing this file with editors that do not support line width greater than 255 characters.

DO NOT use MS-DOS EDIT on this file!

The entry for the CUCM follows the form of a Compact Dual Port Memory I/O module with 64 bytes of input and 64 bytes of output. The standard entry used in Modsoft V2.4 is shown below:

```
CUCM ,214,0,64,64,NR&D Universal Comm,0,L0127,2,0000
1234567890123456789012345678901234567890123456789012345678901234567890123456789
```

The fields are comma separated.

- The first 10 characters are the Name of the module.
- The 214 is the next entry in the list of available devices. If you are adding this line, choose the next free number in the list.
- The 0 in character position 16 indicates that other modules may be inserted in this drop.
- The 64 in character positions 18 and 19 set the number of INPUT bytes. A value of 64 provides 32 WORDS of input (3x registers)
- The 64 in character positions 21 and 22 set the number of OUTPUT bytes. A value of 64 provides 32 WORDS of output (4x registers)
- The next field is the text description (19 characters max.).
- The 0 in position 40 determines that the module is a discrete module and may take 0x, 1x, 3x, 4x references.
- The module ID is L0127.
- The 2 that follows signifies that the CUCM is a Compact DPM module.
- The last 0000 tells the T_MODULE.LmsSlotData.a to use the default module bits.

It is possible to modify the width of the INPUT bytes and OUTPUT bytes to adjust the CUCM for a unique application. The Compact rack only allows 64 words total for the rack so it may be desirable to...
reduce the number used by the CUCM to allow for other I/O. For example, the Input and Output bytes might be set down to 10 bytes each to allow 5 words of input and 5 words of output to the CUCM and leave room for other I/O in the rack.

NOTE: If the entry in the Traffic Cop configuration file is altered, all CUCMs in the PLC system will use this entry. Also, special care will be needed during future updates of Modsoft to carry the altered setting to the new revision.
The register configuration of each module is controlled by the ModConnect tool in Concept. The ModConnect tool adds devices to Concept that were not originally available when Concept was developed. To accomplish this, the user must copy a .mdc file to the \Concept directory. The .mdc file for the CUCM is available on the website. Download the concept21.zip file, and extract either the Nrd_w95.mdc, or the Nrd_wnt.mdc file to the \Concept directory.

Next open the ModConnect tool from the Start menu. From the file menu, choose Open Installation File. The appropriate .mdc file should appear in the list of files from which to choose. Click the .mdc file, then click OK. The Select Module dialogue box will appear, allowing the user to choose one of the CUCM configurations that are available. Choose the appropriate module, and click Add Module. Concept now has all the information needed to configure a Compact PLC for the CUCM.

Note: It is not recommended to add more than one CUCM configuration to the Concept Modconnect tool. Only choose the one that is most appropriate to the needs of the application.
Appendix F

NR&D on the Internet

Niobrara offers product information, firmware and software upgrades, user manuals, and technical support via the Internet at:

http://www.niobrara.com

For technical support questions e-mail: techsupport@niobrara.com

The memory of the CUCM is divided into separate areas including PLC Rack Input (3x) 16-bit register, PLC Rack Output (4x) 16-bit registers, and four files (6x).

**PLC INPUTS (3x)**

The CUCM has 60 implemented 3x registers. The first 32 are available to the Compact PLC through the backplane and are read-only to the PLC. Inputs 1 through 4 default to the status and line number displays for Applications 1 and 2. The INPUT registers are arranged in Modicon bit order with the bits 1-16 in MSB-LSB.

### PLC OUTPUTS (4x)

The CUCM has 2048 implemented 4x registers. The first 32 are available to the Compact PLC through the backplane and are read/write from the PLC. The INPUT and OUTPUT registers are arranged in Modicon bit order with the bits 1-16 in MSB-LSB.
